TREATMENT OF EARLY SYPHILIS WITH PENICILLIN

THOMAS H. STERNBERG, M.D.
Los Angeles
and
WILLIAM LEIFER, M.D.
New York

In a previous paper[1] we presented the results of the treatment of early syphilis with the twenty-six weeks' oxophenarsine hydrochloride-bismuth schedule which was adopted by the Army in July 1942. It was shown that this schedule was of relatively low toxicity and yielded a high proportion of satisfactory therapeutic results. Its eventual replacement as the standard therapeutic procedure came about mainly because it failed to meet Army requirements for a short intensive schedule for soldiers under field or combat conditions and because of the demonstration that penicillin was a potent antisyphilitic agent.

Encouraged by the pioneer experiments of Mahoney, Arnold and Harris,[2] the extensive investigations of the Subcommittee on Venereal Disease, National Research Council[3] and certain pilot studies within the Army,[4] the Surgeon General in 1944, on recommendation of the National Research Council, instituted penicillin treatment for all soldiers with early or latent syphilis. The schedule called for 40,000 units of sodium penicillin in aqueous solution or isotonic solution of sodium chloride to be given intramuscularly every three hours for sixty doses, a total of 2,400,000 units in seven and one-half days. The procedure was first put into practice in the European Theater of Operations in June 1944, and in October 1944 it was instituted throughout the entire Army.[5]

The present report is based on an analysis of the records of 1,400 soldiers with early syphilis treated by the foregoing schedule between June 1944 and Feb. 1, 1945.

MATERIALS AND METHODS

The Army requires that all pertinent clinical, therapeutic and laboratory data relative to each soldier infected with syphilis be entered by the medical officer in a special form called the "syphilis register." This register ordinarily accompanies the soldier in his travels and forms a permanent record of his case. When the prescribed follow-up examinations have been completed with satisfactory results (clinical normality, serologic negativity and normal findings in the cerebrospinal fluid), the register is officially closed and sent to the Office of the Surgeon General for survey and filing.

In the case of soldiers separated from the service because of demobilization or disability prior to the termination of the prescribed follow-up, the register is transmitted to the Surgeon General at once. However, immediately before separation the soldier is examined for evidence of relapse, and a serologic test for syphilis is performed. In the event that clinical evidence of relapse is found, the soldier is hospitalized for study and treatment and the appropriate entries are made in the syphilis register prior to its transmission.

Selection of Cases.—The histories in the 1,400 cases on which this study is based were collected in the Office of the Surgeon General between Nov. 1, 1945 and March 1, 1946. All syphilis registers arriving during this period were included in the series, provided that they met the following criteria:

1. The patient must have been separated from the service because of demobilization regulations or because of disability. It is believed that this provision reduced the factor of selection to a minimum, since no man was refused separation because of syphilis except in the presence of clinical relapse or late manifestations of the disease, and either of these events would merely delay the transmission of the register for several weeks to months.
2. The criteria for the diagnosis of primary or secondary syphilis must have been adequate.
3. The treatment must have been initiated before Feb. 1, 1945. This arbitrary date was chosen in order to obtain the longest follow-up period possible.
4. The initial treatment must have been by the prescribed method; that is, the intramuscular administration of 2,400,000 units of penicillin in seven and one-half days.

Material Studied.—Table 1 shows the distribution of the patients according to the stage of the disease and race. There were 600 (42.8 per cent) patients with the disease in the seronegative primary, 564 (40.3 per cent) with it in the seropositive primary and 236 (16.9 per cent) with it in the secondary stage. There were 790 (56.4 per cent) white and 610 (43.6 per cent) Negro patients. All were men between 18 and 38 years.

Treponema pallidum was demonstrated in the lesions in all the cases of seronegative primary syphilis, in 77 per cent of the cases of seropositive primary syphilis and in 41 per cent of the cases of secondary syphilis.

The standard and quantitative Kahn tests were used for diagnostic and follow-up purposes throughout. All patients were hospitalized for at least the period of treatment.

The data have been compiled in tables 2 to 7 inclusive to show the total period of observation, the number of cases in which progress was satisfactory, the cases in which progress was considered unsatisfactory, the types of failures encountered and the results of examinations of cerebrospinal fluid. The follow-up period has been measured from the date that treatment was initiated. Approximately 84 per cent of the patients were observed for longer than nine months.

Table 1.—*Distribution of Patients According to Stage of Disease and Race*

	Number of Patients		Race			
			White		Negro	
Stage of Disease	No.	%	No.	%	No.	%
Seronegative primary	600	42.8	388	64.7	212	35.3
Seropositive primary	564	40.3	304	53.9	260	46.1
Secondary	236	16.9	98	41.5	138	58.5
Total	1,400	100.0	790	56.4	610	43.6

"Satisfactory progress" indicates that during the period of observation the patient showed no evidence of clinical relapse, that the serologic reaction for syphilis became negative or remained negative throughout and that, when examined, the cerebrospinal fluid was completely normal.

"Unsatisfactory progress" included all forms of infectious relapse, as well as possible reinfections, serologic relapse, abnormalities of the cerebrospinal fluid and doubtful or positive serologic reactions for syphilis at the last test, regardless of the length of observation.

REACTIONS

The material studied does not permit an accurate estimation of the frequency of the various reactions, since it is probable that many minor evidences of toxicity either were overlooked or were not entered in the registers. Urticaria and various other cutaneous eruptions presumably due to penicillin were not uncommon; febrile Herxheimer reactions were frequently noted. Of most importance in this respect is the fact that during the three month period when the case histories were being selected not a single serious reaction to penicillin was discovered, and in no instance was it necessary to discontinue treatment.

RESULTS OF TREATMENT

Seronegative Primary Syphilis.—The results of treatment of seronegative primary syphilis are shown in table 2. Of the 600 patients in this group, 517, or 86 per cent, had been observed for more than nine months. Five hundred and sixty-six, or 94.3 per cent, were progressing satisfactorily at the time of the last observation. A total of 34 patients (5.7 per cent) were classed as progressing unsatisfactorily, and their results were considered failures, in 27 because of infectious relapse and in 7 because of serologic relapse. It is believed significant in respect to reinfection that of the 27 patients with conditions diagnosed "infectious relapse" 9 exhibited a solitary dark field–positive penile lesion associated with a negative serologic reaction. Of the nine lesions, two appeared in less than three months following treatment, two between three and six months, one between six and nine months, three between nine and twelve months and one after twelve months. Six of the 9 patients were Negroes. Thirteen additional patients among the 27 with "infectious relapse" had a monorecidive, but in them the serologic reaction was positive. Seven patients in this group were classified as having serologic relapse, because of a positive Kahn reaction at or prior to the time of the last observation. Two of these were observed for less than three months following treatment, 1 for between three and six months, 3 for between six and nine months and 1 for more than twelve months. It is of interest that of the 34 cases with results considered failures 32 were so classified before twelve months of observation had elapsed. The cerebrospinal fluid of 304 patients in this group was examined and it was entirely normal in all.

Table 3.—*Results of Treatment of Seropositive Primary Syphilis*

Period of Observation, Mo.	Number of Patients	Progress Satisfactory	Progress Unsatisfactory				
			Infectious Relapse	Serologic Relapse	Serum Fast		Abnormal Spinal Fluid
					Doubtful	Positive	
Less than 3	12	4	4	0	1	8	0
3 to 6	25	8	12	5	0	0	1*
6 to 9	65	49	4	5	0	6	1
9 to 12	283	274	0	3	3	8	0
Over 12	174	172	0	1	1	0	0
Total	564	507	20	14	5	17	2
			58*				

* One patient's results recorded twice to indicate the coincidental finding of infectious relapse and abnormal cerebrospinal fluid.

Seropositive Primary Syphilis.—In table 3 are shown the results of treatment of 564 patients with seropositive primary syphilis, of whom 462, or approximately 82 per cent, were followed for more than nine months. Five hundred and seven (89.9 per cent) were progressing satisfactorily at the time of their last observation. Fifty-seven patients (10.1 per cent) were placed in the "unsatisfactory progress" classification because of infectious relapse in 20, serologic relapse in 14, abnormal cerebrospinal fluid in 2 and serum fastness in 22. The results for 1 patient have been entered as failure twice, because of concomitant infectious relapse and abnormal cerebrospinal fluid. Among the 20 patients with infectious relapse there was only 1 with a solitary dark field–positive penile lesion associated with a negative serologic reaction, but there were 12 patients with positive serologic reactions in whom the recurrent infectious lesions were limited to the penis. It is noteworthy that of the thirty-four instances of infectious and serologic relapse all but one occurred before twelve months of follow-up had been obtained. Seventeen serum-fast patients had a positive serologic reaction and 5 a doubtful reaction at the time of the last examination. It is probable that with continued observation some of these reactions would have reversed to negative spontaneously. The cerebrospinal fluid of 287 patients was examined, and it was found normal in all but 2.

Secondary Syphilis.—In table 4 are shown the results of treatment of 236 patients with secondary syphilis, of whom 199, or approximately 84 per cent, were followed for more than nine months. One hundred and ninety-six (83.0 per cent) were making satisfactory progress and 40 (17.0 per cent) unsatisfactory progress at the time of the last observation. Unsatisfactory progress was manifested by infectious relapse in 4 patients, serologic relapse in 6, serum fastness in 27 and abnormal cerebrospinal fluid in 3. The small number of patients with infectious relapse, only 4 in this group, is of possible significance from an immunologic standpoint, although it may be accounted for by overlooked minor mucocutaneous lesions. All the ten instances of infectious and serologic relapse occurred before the twelfth post-treatment month. Of the 27 patients with serum fastness, 20 had a positive and 7 a doubtful serologic reaction at the time of the final examination. There were 3 patients with abnormal cerebrospinal fluids among the 128 that were examined.

Table 4.—*Results of Treatment of Secondary Syphilis*

Seronegative primary.	600	304	304	0	0	0
Seropositive primary..	564	287	285	1	1	0
Secondary............	236	128	125	0	2	1
Total............	1,400	719	714	1	3	1
					5	

Effects of Treatment on the Cerebrospinal Fluid.—As shown in table 5, the cerebrospinal fluid was examined following treatment in 719 (51.3 per cent) of the 1,400 patients. In 79 the examination was performed between three and six months after treatment and in the rest, after six months or more. In only 5 (0.69 per cent) of the seven hundred and nineteen fluids was any abnormality noted, two of these occurring in cases of seropositive primary syphilis and three in cases of secondary syphilis. Moore's classification[6] of cerebrospinal fluid abnormalities was used, one was in group I, three were in group II and one was in group III. In one instance, shown in table 3, a patient had an infectious relapse and an abnormal cerebrospinal fluid concomitantly. No instance of symptomatic neurosyphilis was recorded in this series.

Summation of Treatment Results.—Table 6 shows that of the 1,400 patients on whom this study was based 1,269, or 90.6 per cent, were progressing satisfactorily and 131 (9.4 per cent) unsatisfactorily at the time the final observations were made. The variation in response of the three phases of early syphilis is clearcut. Thus for the period of follow-up available in this study, satisfactory progress was indicated in 94.3 per cent of the group with seronegative primary syphilis, in 89.9 per cent of the group with seropositive primary syphilis and in 83.0 per cent of the group with secondary syphilis. In this series, in 83 per cent of the patients the disease was diagnosed and treated in the primary stage, a percentage consistent with previous reports on Army material.[7] The over-all favorable results of 90.6 per cent are, therefore, to a large extent dependent on this ratio, which is at variance with the usual findings in civilian clinics, in which a considerably higher incidence of late secondary syphilis is encountered.

Table 6.—*Progress of Entire Series of 1,400 Patients, Regardless of Period of Follow-up*

Secondary.............	236	196	83.0	40	17.0
Total.............	1,400	1,269	90.6	131	9.4

COMMENT

It must be emphasized that the results presented in this paper are to be regarded as tentative and not representative of the final percentage of "cure." The period of observation, even for the patients followed for over a year, is still inadequate. Nevertheless, and despite the known exquisite chronicity of syphilis, we venture the opinion that the ultimate results with this therapeutic schedule will not be at great variance with those reported here. With longer observation, some of the conditions now classified as progressing satisfactorily would undoubtedly eventuate in failure. It is not believed that the number of such additional failures would be large, since only three of the seventy-eight instances of clinical and serologic relapse occurred after

Table 7.—*Classification of Treatment Failures According to Stage of Disease, Race and Type of Failure*

a year or more of observation, the majority becoming evident between the third and the ninth post-treatment month. On the other hand, some of the 49 patients classed as serum fast might well progress spontaneously to seronegativity and would then be included in the satisfactory group.

In view of the recent revelations concerning the changed nature of commercial penicillins,[8] any analysis of their therapeutic effectiveness must take this factor into account. It has been shown that commercial penicillins contain varying proportions of one or more of four chemically distinct but closely related crystalline species, termed G, F, X and K. Apparently the earlier penicillins contained chiefly G or F and little X or K. With a change in the producing organism and in the method of manufacture, larger amounts of K appeared, at the expense primarily of G. In animal syphilis, K appears to be relatively ineffective as compared with G, F and X. This is attributed to the rapid destruction of K in the body, probably by serum. As far as can be learned, the change in commercial penicillins came about in 1945. Since all the patients in our series were treated prior to Feb. 1, 1945, presumably with penicillins of good potency, the results may be much superior to those obtained today with an identical schedule of treatment.

It is more difficult to understand why certain persons in the same stage of syphilis respond favorably to a given dose of drug while others do not. This may be due to the drug itself, which may be deteriorated or of low potency; to some unknown difference in the immune responses of the patient, resulting in an inability to utilize the drug properly or to muster satisfactory defenses of the tissue, or finally, to a difference in virulence or drug susceptibility of the infecting organism. There is evidence, as already presented, to show that commercial penicillins have not always been of the same character or potency and, in fact, that they may vary in these respects from day to day in the hands of the same producer. However, this explanation cannot account for all failures, for even with the best of the arsenical-bismuth schedules a certain percentage of infected persons failed to respond, and it must be anticipated that there will be a similar group of failures even with the best penicillins or with penicillin-arsenic-bismuth combinations. It must therefore be assumed that subtle differences in the biologic interrelationship of the human being and the micro-organism lie at the root of an appreciable percentage of failures in treatment. These differences appear to be quantitative rather than qualitative, since most patients who relapse after a given course of treatment respond subsequently to an intensified and more prolonged therapeutic regimen. And, conversely, almost all patients can be made to fail when given a grossly inadequate amount of drug.[5]

In table 7 are presented in detail the failures observed in the present series. Most striking are the differences in rates of failure between the races in all three phases of early syphilis. There were 40 (5 per cent) patients with failures among the 790 white patients, as contrasted with 92 (15 per cent) among the 610 Negro patients. We hesitate to ascribe this disparity in results to a dissimilarity in host-parasite relationship between the races. Furthermore, other studies of similar material do not support such a concept. On the other hand, it may be attributed to a higher incidence of reinfection among Negroes, as suggested by the occurrence of twenty-six (4.2 per cent) instances of monorecidive in them as compared with eleven (1.4 per cent) instances in white patients. However, if reinfection is to serve as an explanation for the considerably higher incidence of serologic relapse and serum fastness in the Negro group, it must be assumed that many of these patients either concealed or did not report the early lesions or that the lesions were overlooked by the medical officer or that lesions failed to develop early in the course of their reinfection. If it is conceded that reinfection is possible—and most syphilologists do concede this—it should be expected to occur with greater frequency in a group such as this, in which 83 per cent of the patients were treated intensively in the primary stage of the disease with a short schedule and without benefit *of the prophylactic effects of a bismuth preparation.* It is of interest and possible significance in this connection that the incidence of "infectious relapse" in this series was 4.5 per cent in seronegative primary and 3.5 per cent in seropositive primary syphilis, as contrasted with 1.7 per cent in secondary syphilis. Moreover, reinfection should be expected to occur with much greater frequency in the Negro group, since the syphilis rate of Negro troops has been consistently twelve to fifteen times that of white troops. Since the alternative to this hypothesis must involve a presumed racial difference in the mechanisms of biologic response to the disease, of which there is no proof at the moment, it would seem to us that reinfection in intensively treated patients with primary syphilis is a much more important factor in evaluating therapeutic results than has been generally conceded.[9] The burden of distinction between monorecidive and reinfection might well be shifted to those who contend that a lesion is a monorecidive mainly because the circumstances of the case do not happen to fit the almost impossible criteria for reinfection.[10]

SUMMARY

1. An analysis was made of the Army records of 1,400 men with early syphilis treated with 2,400,000 units of penicillin in aqueous solution or isotonic solution of sodium chloride prior to Feb. 1, 1945.

2. There were no severe toxic reactions, and all patients completed the prescribed schedule of treatment.

3. Approximately 84 per cent of the patients were observed for over nine months following treatment.

4. Satisfactory progress was obtained in 94.3 per cent of 600 cases of seronegative primary syphilis, in 89.9 per cent of 564 cases of seropositive primary syphilis and in 83.0 per cent of 236 cases of secondary syphilis.

5. The cerebrospinal fluid was examined following treatment in 719 patients: it was normal in 714 and abnormal in 5 (0.69 per cent).

6. The high over-all satisfactory progress rate of 90.6 per cent, admittedly tentative because of inadequate

follow-up, was attributed to the considerable proportion of cases of the disease in the primary stage (83.1 per cent) and to the fact that the patients were probably treated with penicillins of satisfactory potency.

7. The rate of failure was approximately 5 per cent in the 790 white patients and 15 per cent in the 610 Negro patients, and the implications of this disparity in respect to reinfection were discussed.

ABSTRACT OF DISCUSSION

Dr. Grant Morrow, San Francisco: Dr. Sternberg has shown that penicillin is as active a spirocheticide as arsenic compounds or bismuth preparations. The results are equal to or better than those obtained with the five day drip, the eight day drip or the Eagle method. The toxic reactions to penicillin are negligible when compared with 1 death for each 500 patients treated with the five or eight day method and about 1 in each 2,000 treated by the Eagle regimen. There is no discrepancy between the white and the Negro race. There is a higher incidence of reinfection in the Negro race. Dr. Sternberg has presented 9 cases of relapse in the seronegative primary group and 1 case in the seropositive group. All the patients in these cases had solitary dark field-positive lesions and were seronegative. It is impossible for their conditions to be relapses. They are definite reinfections. When relapse follows rapid treatment, the serologic reaction drops in titer, though rarely to negativity, and then rises during the next four to eight weeks, when lesions appear. When this happens the lesions are usually multiple papules. If there is a dark field-positive lesion and the serologic reaction is negative, the condition is one of reinfection, not of relapse.

At the University Hospital in Ann Arbor, Mich., there was a man with a primary dark field-positive chancre. In his wife, results of physical and serologic examination were negative. The man received rapid treatment. They returned in two months. Results of his physical and serologic examination were negative. The wife had a dark field-positive chancre. She received rapid treatment. Again in two months they returned, and the husband had a new dark field-positive chancre in a different location. The wife had a negative reaction. Both patients were then retreated, although there was evidence of syphilis in the husband only. The results of clinical and serologic examination of each have remained negative more than a year. The United States Public Health Service has had many such experiences and has aptly termed this "ping-pong syphilis."

Dr. Charles R. Rein, New York: Dr. Sternberg has asked me to discuss our experiences with the serologic follow-up of patients with penicillin-treated syphilis. In the Division of Serology at the Army Medical Center, we had the opportunity of performing a battery of serologic tests with serums of such patients at weekly and monthly intervals. It was possible to distinguish between relapse and reinfection by carefully conducted serologic studies. Following penicillin therapy in patients with early syphilis, there was usually a progressive reduction in serologic titer. In reinfection the patient attained and maintained complete seronegativity followed by the development of a dark field-positive seronegative lesion at a new site. Shortly afterward in such patients there developed seropositive reactions with rapidly increasing titers. In treatment failures or relapse there was noted a sudden increase in serologic titer, followed in about one month by clinical evidence of a mucocutaneous relapse. If penicillin-treated patients are subjected to serologic examinations at weekly or monthly intervals, it is possible to predict a clinical relapse about one month before there is any clinical evidence by the increase in serologic reaction following seronegativity. It is of utmost importance, therefore, to educate these patients to the importance of reporting to the physician at monthly intervals for at least one year following the completion of penicillin therapy for serologic and clinical examinations.

PENICILLIN IN THE TREATMENT OF NEUROSYPHILIS

A Study of One Hundred Cases Followed Twelve Months or More

AUGUSTUS S. ROSE, M.D.
and
HARRY C. SOLOMON, M.D.
Boston

During the twenty-six months between Feb. 1, 1944, and April 1, 1946, 236 patients with neurosyphilis were treated with penicillin at the Boston Psychopathic Hospital. Of these, 12 patients have died, follow-up of 14 patients has been lost from the clinic and 210 are now under follow-up. This report is concerned chiefly with the first 100 of the cases which have been followed one year or more after treatment. A large percentage of patients were psychotic and were regularly committed as insane. Many had been patients in other state mental hospitals and were transferred to the Boston Psychopathic Hospital for the investigative therapy. After treatment, patients were discharged to the community if clinical improvement permitted and were seen in the outpatient department for periodic examination. Otherwise, they were transferred to the Metropolitan State Hospital in Waltham, Mass., where follow-up examinations could be made by those of us who administered the therapy. If retreatment became necessary, patients were readmitted or retransferred to the Boston Psychopathic Hospital. Patients who had previously received fever therapy within one year and patients with conditions which were in a developing remission from previous therapy were excluded.

Table 1.—*The Results of Combined Penicillin-Fever Therapy in Neurosyphilis*

Diagnosis	Total Patients	Patients Improved, No.	Patients with No Change, No.	Patients Worse, No.	Patients Retreated, No.
Dementia paralytica......	75	52 (69%)	21	2	29 (38%)
Tabes dorsalis............	10	7	3	0	1
Meningovascular disease..	10	2	8	0	2
Optic atrophy............	5	1	3	1	4
Total..................	100	62	35	3	36

METHODS OF TREATMENT

As fever therapy is known to be effective in late neurosyphilis and as the value of penicillin was undetermined, at the beginning of our investigations it seemed safer for the patient to combine the two methods. Therefore, a program of administering malaria or fever in a fever cabinet in amounts equivalent to approximately one half of the generally accepted course of fever was instituted and is still being carried out in the majority of cases. This consists of four to six paroxysms of malarial fever with temperatures above 104 F. or a total of twenty hours of temperature above 105 F. in the fever cabinet. Penicillin was given concurrently or in succession with the "one-half course" of fever therapy. In a few cases (19) penicillin was given

Read before the Section on Dermatology and Syphilology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

without fever therapy. No other form of antisyphilitic treatment was administered. If the patient's condition indicated the need for more treatment, penicillin was repeated in the same amount and frequency as the first course. Fever therapy was not repeated.

No rigid criteria were laid down for the second or third course of penicillin, since an effort was made to study each individual case and determine its need from time to time. However, patients who showed either clinical or spinal fluid relapse were retreated. Also, patients who failed to show improvement in clinical condition and spinal fluid at the end of two months were given additional treatment with penicillin. If cell count and total protein contents of the spinal fluid remained at abnormal levels at six months, a repeat course of penicillin was given, regardless of clinical status.

Table 2.—*Comparison of Results by Different Methods of Treatment*

Methods of Treatment	Total Patients	Patients Improved		Patients with No Change, No.	Patients Worse, No.	Patients Retreated	
		No.	%			No.	%
Penicillin plus malaria...	60	40	66	20	0	20	33

Penicillin alone..........	19	11	58	7	1	11	58
Total................	100	62		35	3	36	

A total of 3,000,000 units of penicillin, given intramuscularly, was used arbitrarily as a course of treatment. The time interval of injection and number of units per injection were varied according to a plan designed to give data for comparison. All the patients in the 100 cases herein reported received 3,000,000 units of penicillin as a course.

DIAGNOSTIC CLASSIFICATION

For purposes of simplification, all patients with definite symptoms of mental disorder are included under the diagnosis of dementia paralytica. Many of these patients showed neurologic signs of tabes dorsalis, and several had primary optic atrophy. The patients classified as having tabes dorsalis and optic atrophy had symptoms and signs of those disorders without psychiatric symptoms. Under the diagnosis of meningovascular neurosyphilis are the patients with pupillary abnormalities yet without symptoms and patients who gave evidence of recent or remote cerebral vascular occlusion.

CLINICAL RESULTS

The evaluation of clinical results of treatment in a disease so complex as late symptomatic neurosyphilis is extremely difficult. Psychiatric symptoms may be affected, as in the nonsyphilitic patient, by changes in the environment, by alterations in the general physical status or by the administration of active treatment. Furthermore, patients may show improvement in some symptoms and progression in others. New symptoms such as convulsions may appear while all other symptoms improve. To obviate as many of these difficulties as possible, we present the clinical results only in cases followed at least one year, and we classify the status of the patients as "improved," "no change" and "worse." These categories represent the over-all clinical picture of the patient on or about April 1, 1946, as compared with the total picture before treatment. Table 1 shows the clinical results of the 100 patients divided on basis of diagnosis. Emphasis is placed on the column "Patients Retreated." We interpret this to be a rough estimate of the adequacy of the treatment as judged by clinical and laboratory data during the period of follow-up.

* Spinal fluid examination was not done on 5 of the 100 patients at one year or after.

It is evident from table 1 that the number of patients is too small to permit comparison of results between the diagnostic groups. Nevertheless, it is clear that 69 per cent improvement in the cases of dementia paralytica and 62 per cent improvement in the whole group points to results which compare favorably with older methods of treatment. Thirty-six of the 100 patients required retreatment with penicillin.

Attention is drawn to the cases of optic atrophy. Although 4 of the 5 patients required retreatment, only 1 showed progression of visual loss and 1 patient showed improvement. In the latter patient there was improvement in visual acuity and also a widening of the peripheral fields.

Comparison of results by the three different methods of treatment, as shown in table 2, is subject to confirmation because of the unequal number of cases. Of the 60 patients treated with penicillin combined with malaria, 40 (66 per cent) are improved, 20 have shown no change and 20 (33 per cent) required retreatment. The group treated with penicillin combined with fever in a fever cabinet and those treated with penicillin alone showed a somewhat smaller percentage of improved conditions.

The results obtained by the four different schedules of administration of penicillin are compared in table 3. Again, the unequal number of patients in each group does not permit definite conclusions. However, the trend shown by the percentage of patients requiring retreatment is probably significant, for comparable figures are obtained in our entire series of 210 cases. That is, patients given penicillin over a period of fifteen days require retreatment in fewer instances than those receiving penicillin in five days.

It is of interest to segregate the 75 cases of dementia paralytica for analysis of results (table 4). Fifty-two patients (69 per cent) are improved, 21 have shown no change and 2 are worse. Twenty-nine patients (38 per cent) required retreatment with penicillin. Forty-nine of the improved patients have returned to the community and have regained approximately their prepsychotic socioeconomic status. Although these results may be considered good, 38 per cent requiring retreatment points out that the original treatment was not sufficient.

Twelve of the patients with dementia paralytica were treated with penicillin alone. Of these, 8 are improved, 3 have shown no change and 1 is worse. The last patient and 1 of the 3 showing no change as of April 1, 1946 have since been given fever therapy. Nine (75 per cent) of the 12 patients required retreatment with penicillin. The small number of patients in this group makes it impossible to draw any conclusion other than that 3,000,000 units of penicillin is insufficient treatment for dementia paralytica.

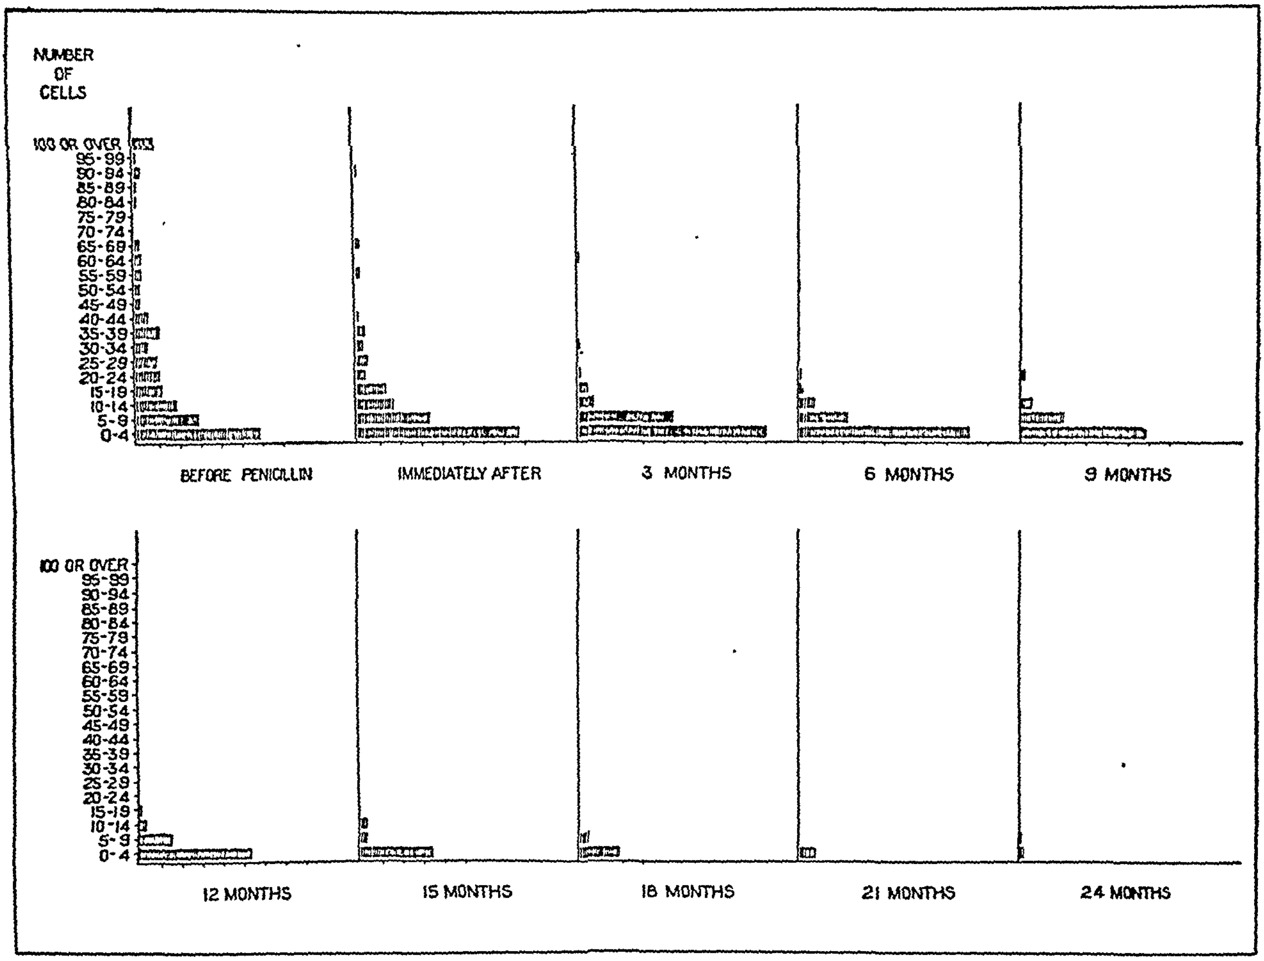

Chart 1.—Follow-up on the white cell count in the spinal fluid after patients were treated with penicillin. (One mark indicates 1 case.)

RESULTS OF EXAMINATION OF SPINAL FLUID

Spinal fluid was obtained in each case before treatment, immediately after treatment and at intervals of at least every three months thereafter. On each specimen the cell count and total protein content were determined by the hospital laboratory. The Wassermann Laboratory of the Department of Public Health of the Commonwealth of Massachusetts performed the titrated Kolmer-Wassermann reaction on each specimen. The Wassermann reaction is carried out in six dilutions of spinal fluid as follows: 0.1 cc., 0.2 cc., 0.4 cc., 0.6 cc., 0.8 cc. and 1.0 cc.

Charts 1, 2 and 3 portray the determinations of cell count, total protein content and Wassermann reaction respectively on all patients treated with penicillin from whom spinal fluid was obtained three months or more after treatment. In each figure one mark represents 1 case. In chart 3 each mark is recorded on the basis of the weakest dilution of spinal fluid in which the Wassermann reaction was found positive. It is observed that the number of cases followed decreases with each quarterly period of follow-up. In spite of this decrement, a number of changes in the direction toward normal in the abnormalities of the spinal fluid are observable.

Before treatment the cell count (chart 1) and total protein content (chart 2) are above normal in a large number of cases.[1] The relative number of patients showing normal determinations increases in each of the follow-up periods. The cell count is seen to return to normal somewhat earlier than does the total protein content. A decrease in the intensity of the Wassermann titration (chart 3) occurs, but this change is less rapid than those of cell count and total protein content. The number showing a negative Wassermann reaction at any period of follow-up is few. In spite of these trends toward normal, it is evident that there are some cases in the latter periods of observation which will still show strong abnormalities of the spinal fluid.

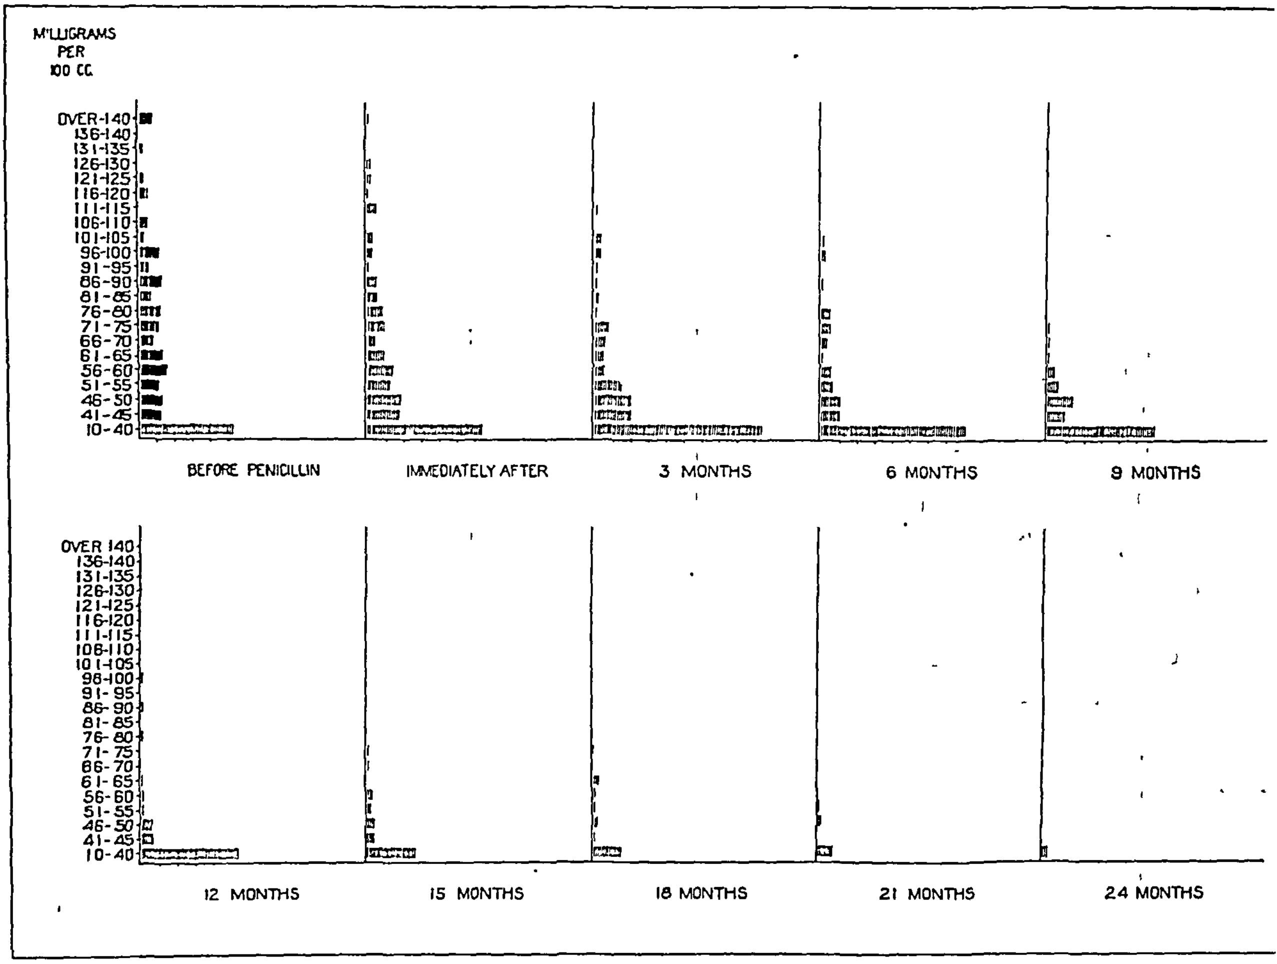

Chart 2.—Follow up on the total protein content of the spinal fluid after patients were treated with penicillin (One mark indicates 1 case.)

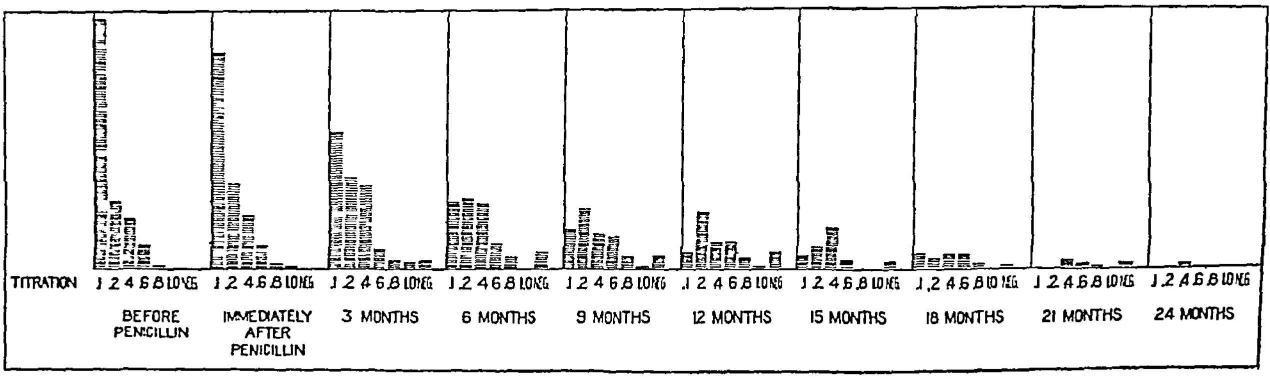

Chart 3.—Titrated Wassermann (Kolmer) reaction of the spinal fluid after patients were treated with penicillin (One mark indicates 1 case.)

The changes in the spinal fluid shown by the large group of cases are also to be found in the 100 cases followed one year or more (table 5). The majority of the patients have normal cell counts and total protein contents after treatment, and the shift in Wassermann reaction toward a weaker titration is definite. Eleven patients at one year or more after treatment have negative Wassermann reactions.

---

[1] The rather large number of patients showing normal cells and total protein content before treatment is explained by the fact that many of these patients had received chemotherapy previously in other hospitals.

Because the majority of patients in this study received a short course of fever therapy as well as penicillin, the question is raised as to whether the changes observed are due to fever therapy. A survey of results of examination of spinal fluid in the 19 patients treated with penicillin alone reveals similar and comparable changes to the larger group, although the shift in the titration of Wassermann reactions was less striking. This, together with published data from other clinics, demonstrates that penicillin alone will effect a change in the spinal fluid. Since the amount of fever therapy administered to these patients is considerably below that which experience has proved necessary for the best treatment of this disease, we believe that the results to be obtained at the end of several years will give evidence of the usefulness of penicillin.

DEATHS

Of the 12 deaths which have occurred in the 236 patients treated during the twenty-six months, 6 are accredited to dementia paralytica, 3 to accidental causes, 1 to sudden cardiac failure, 1 to bronchopneumonia and 1 to ruptured peptic ulcer. In 1 patient dying of dementia paralytica it was felt that penicillin given during an acute, extremely overactive psychosis may have contributed to the death. At least no quieting effect was obtained, and it is possible that penicillin intensified the symptoms. In no other case did it appear that treatment contributed to the fatal outcome.

COMMENT

Although past experience had demonstrated the many difficulties in evaluation of new treatments of late symptomatic neurosyphilis, nonetheless the advent of penicillin into the treatment of neurosyphilis was greeted with great optimism. The relatively short space of time required for its administration, its safety and the fact that it can be given during the course of therapeutic malaria were considered great advantages. Furthermore, our program of a short course of fever therapy had the advantage of reducing the complications and decreasing the natural discomforts of the patient of longer courses of fever. After two years' experience with penicillin our enthusiasm has been tempered, and we have become aware of the limitations of this treatment as well as the advantages. During the early months of our studies in 1944 we were impressed with the therapeutic potency of penicillin as shown by the relative frequency of an immediate reaction of intensification of symptoms followed by the subsidence of tremors, dysarthria and, in some instances, memory defects. At that time we were concerned lest in giving 3,000,000 units we were giving an unduly large quantity of the drug. But as patients were followed and more and more cases of varying types were added to the series, doubts about the significance of our early observations began to creep in. Early in 1945 the arbitrarily selected course of 3,000,000 units of penicillin was increased to 6,000,000 units. It had by then become evident that the need for retreatment was too frequent to consider the treatment as satisfactory, and we did not wish to complicate the investigation by increasing the amount of fever. It is possible that some of these clinical observations may be attributed to the changing qualities of commercial penicillin, as recently pointed out in The Journal. However, it is also possible that the processes of recovery following a short course of fever therapy and penicillin are less adequate than those which accompanied the older methods of treatment. But, in spite of a reduced enthusiasm engendered by experience, the results obtained are creditable and, at least by the methods of evaluation used, are comparable to older methods of treatment. If these results withstand the test of time, considerable progress will have been made in the treatment of late neurosyphilis.

SUMMARY AND CONCLUSION

1. Two hundred and thirty-six patients with neurosyphilis were treated with penicillin between Feb. 1, 1944 and April 1, 1946. Of these, 210 are now being followed. The clinical results in the first 100 cases followed one year or more are presented. The results of examination of the spinal fluid of all patients on whom an examination was obtained at least three months after treatment, as well as the 100 cases followed a year, are tabulated.

2. The majority of patients were given a short course of fever therapy in combination with penicillin. No other antisyphilitic treatment was given. If more treatment was needed, administration of penicillin was repeated.

3. Each patient was given 3,000,000 units of penicillin intramuscularly as a course of treatment. Intervals of injection and the number of units per injection were varied according to plan.

4. Clinical results of the 100 patients followed one year or more show 62 improved, 35 with no change and 3 worse. Thirty-eight patients were retreated with penicillin.

5. Following treatment the cell count and total protein contents of the spinal fluid return toward normal in from three to six months and six to nine months respectively. The strength of the Wassermann titer decreases more slowly. Of the 100 patients followed a year or more, 11 have a negative Wassermann reaction.

6. The need for retreatment in a little more than one third of the cases followed one year or more indicates that 3,000,000 units of penicillin combined with a short course of fever therapy is not optimum treatment for late symptomatic neurosyphilis.

ABSTRACT OF DISCUSSION

Dr. Paul A. O'Leary, Rochester, Minn.: An interesting feature of penicillin therapy and neurosyphilis is the low incidence of asymptomatic neurosyphilis noted in the patients with early syphilis treated with penicillin. Including all patients with early syphilis, even those who have had their disease for two years, the incidence of asymptomatic neurosyphilis is approximating only 2 per cent. After World War I certain German physicians expressed the belief that arsphenamine per se was a prominent factor in increasing the incidence of neurosyphilis. The fact that asymptomatic neurosyphilis has been found in about 15 per cent of the patients treated with arsenic and is now observed in only 2 or 3 per cent of those treated adequately with penicillin is of more than passing interest. Two years ago my experience with penicillin given alone led me to believe that it was ineffective in the treatment of patients with neurosyphilis. I then started amplifying their treatment course by combining penicillin and fever therapy. By so doing the results of fever therapy have been improved by about 5 to 10 per cent. In other words, the combination of malaria therapy and penicillin given concurrently is superior to either malaria or penicillin therapy when employed individually. The improvement in the serologic reactions of the spinal fluid of patients with neurosyphilis is the outstanding benefit that follows penicillin therapy. Thus far the number of patients in whom the spinal fluid reactions have been improved is much greater than are those in whom all the factors in the spinal fluid tests have been reversed to normal. From the clinical standpoint the good effects following penicillin therapy in patients with symptomatic neurosyphilis may be classified as "tonic." I have never seen a clearcut clinical remission develop in a patient with frank dementia paralytica of any type from penicillin alone, and the partial remissions that occur not only are incomplete but are of short duration. However, penicillin plus fever therapy produces complete remissions. The "tonic" effects, such as gain in weight and improvement in the somatic complaints that occur following penicillin therapy in neurosyphilitic patients, seem to be the outstanding effects. I have noted improvement in the lightning pains of patients with tabes dorsalis. Irrespective of whether the tabetic patient is serologically negative or positive, some decrease in frequency of the pains as well as in their severity has been noted in about 25 per cent of the cases. The future of penicillin-malaria therapy in patients with tabetic optic atrophy offers slight promise. The combination of fever and penicillin is offering at the moment a little encouragement in that more cases are now encountered in which the progressive loss of vision is stopped. The results are erratic following use of penicillin in the treatment of meningovascular neurosyphilis. In occasional cases the serologic reversals to negative are striking, but such results are so irregular and unpredictable that I do not believe that they warrant the use of penicillin alone in such cases. In my experience the results from the use of penicillin given intravenously have been better than when it is administered intramuscularly; however, the technical difficulties, such as the inconvenience and phlebitis, are too great to make its use practical.

Dr. Norman N. Epstein, San Francisco: I appreciate the difficulty of presenting therapeutic results in this manifestation of syphilis. It is hard to describe on the blackboard or on paper the clinical condition of the patients with this condition. It also must be appreciated that it is difficult to evaluate this new remedy penicillin. At present there is no unanimity of opinion as to its value therapeutically, how it should be administered or what the dose should be. Therefore, those who have attempted to treat neurosyphilis with penicillin have had to guess at the optimum therapeutic regimen. My colleagues and I began to treat neurosyphilis with penicillin in March 1945. Since then we have treated 58 patients with neurosyphilis of various types. The plan consisted in the administration of 40,000 units of sodium penicillin intramuscularly every three hours for fourteen days, a total of 4,500,000 to 5,000,000 units being given. Fever therapy was combined with the penicillin therapy. The patient received artificial fever every three or four days during the course of penicillin therapy. Fever was produced by the blanket method. The temperature was elevated to 104 or 105 F. and maintained for five hours at each session. The patient received a total of ten such episodes. When he left the hospital, he was given it weekly, so that he had a total of fifty hours of fever and 4,500,000 to 5,000,000 units of penicillin. These patients have been observed only a short time, a few only as long as eleven months. Sixteen have had their spinal fluids rechecked more than once. Therefore, any conclusions are simply impressions. The patients who had symptoms of meningovascular syphilis, such as transient paralyses, severe headache or eye symptoms such as diplopia, improved remarkably. Those with acute mental disturbances of dementia paralytica, such as disorientation, confusion and excitement, did well also. I think that they did better with penicillin and fever than with fever alone. The patient with the tabetic form of dementia paralytica did no better than when fever only was given. The effects of penicillin and fever therapy on the spinal fluid findings impressed us. Sixteen patients had rechecks of their spinal fluid; in 8 of these the formula of the spinal fluid changed from that of group 3 to minimal changes, i. e., group 1. Protein content, colloidal gold curve and the Wassermann reaction decreased decidedly in character. It was astonishing to see a colloidal gold curve of 5554320000 flatten out to negative in a short period. In the cases in which we have had the opportunity to check several months later such improvement was sustained.

Dr. Louis A. Brunsting, Rochester, Minn: I am sure the essayists will agree that the treatment of syphilis with penicillin is still in the experimental stage and that it will take years to make a proper appraisal; it seems that penicillin alone is not adequate, especially in neurosyphilis. In combining penicillin with forms of fever therapy, it has been my experience that a course of penicillin treatment is useful as an introductory phase of treatment for patients who have a pronounced degree of meningovascular involvement or an agitated stage of paresis. Frequently a course of penicillin will reduce the fulminating process so that fever treatment can be given with less risk of upsetting the balance. A small group of patients have been given penicillin intramuscularly in combination with peanut oil and beeswax, and the results have been equal to those in cases in which penicillin has been given round the clock every three hours in aqueous solution, and by this method some of the hospital expense can be spared.

Dr. Augustus S. Rose, Boston: I am glad that those who discussed the paper brought out the fact that we are not really recommending for general use the schedule of treatment which we have here presented. We have tried only to *evaluate the system of therapy as described and present our* data in as unbiased a way as is possible. It would appear that the treatment which we have administered to these patients, namely, 3,000,000 units, plus what we have termed one-half course of fever therapy, is not sufficent for dementia paralytica.

EARLY CONGENITAL SYPHILIS

Treatment of Two Hundred and Fifty-Two Patients with Penicillin

The avowed purposes of this study were to evaluate the effects of sodium penicillin in the treatment of early congenital syphilis, to find the best means for using this drug alone and to discover criteria by which results might be predicted. Observations incident to treatment of 252 infants in five cooperating university clinics have furnished a wealth of information toward these ends. The recent joint statement issued by the Committee on Medical Research, the United States Public Health Service and the Food and Drug Administration[1] indicates that efforts to relate results quantitatively to various dosage schedules may be partially invalidated. There have been changes in the purity, potency and composition of commercial peni-

Read before the Section on Dermatology and Syphilology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

From the Tulane University of Louisiana School of Medicine (Drs. Platou and Hill), the University of Pennsylvania School of Medicine (Dr. Ingraham), the Johns Hopkins University School of Medicine (Dr. Goodwin), the University of Texas School of Medicine (Drs. Wilkinson and Hansen) and Emory University School of Medicine (Dr. Heyman).

This report represents work performed under several contracts recommended by the Committee on Medical Research of the Office of Scientific Research and Development and the respective universities represented by the authors. Investigation is now being continued under the auspices of the United States Public Health Service, following termination of contracts of the Office of Scientific Research and Development.

[1] The Changing Character of Commercial Penicillin, with Suggestions as to the Use of Penicillin in Syphilis, Committee on Medical Research, the U. S. Public Health Service, and the Food and Drug Administration, Joint Statement, J. A. M. A. 131: 271 (May 25) 1946.

cillin mixtures furnished to us since this study began. There have also been considerable variations in the actual amount of penicillin in individual vials labeled as containing 100,000 units.[2] Though the extent to which these changes affect results herein reported has not been entirely clarified, they may well modify our conclusions.

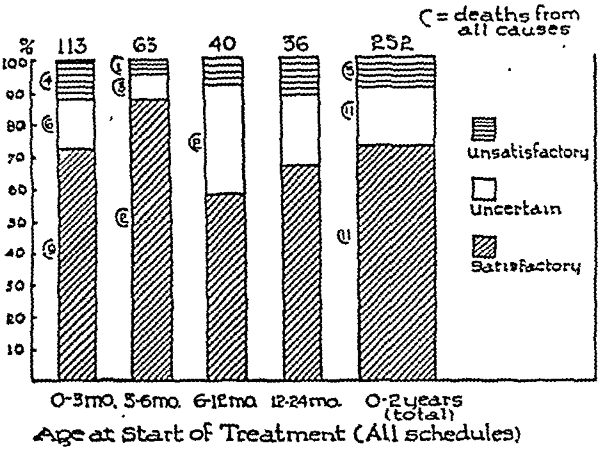

Chart 1.—Outcome by age at start of treatment.

The infants in this series were treated in the period between April 1944 and January 1946. Two hundred and nineteen of them were Negro and 33 were white; there were 118 boys and 134 girls. One hundred and thirteen infants were under 3 months of age, 63 between 3 and 6 months; 46 were treated in the second half of the first year, and 36 were treated during the second year of life.

An empiric scale has been used to judge the clinical severity of the disease: grade 4 indicates a florid example, specifically including demonstration of treponemes, characteristic osseous changes and abnormalities in the spinal fluid. Grade 3 is similar but lacks any one of these three objective demonstrations. Grade 2 has only one of them, and grade 1 presents undoubted manifestations which are proved to be syphilitic only by appropriate serologic tests. A plus sign following any of the first three designations indicates that the examiner believed that the case would fall in the next higher group, but one specific portion of the examination was omitted or was unsatisfactory. A negative status is of course synonymous with latency in this scheme of classification. For purposes of this study, the disease of patients graded 2 plus or more was considered "severe," that of the others "mild."

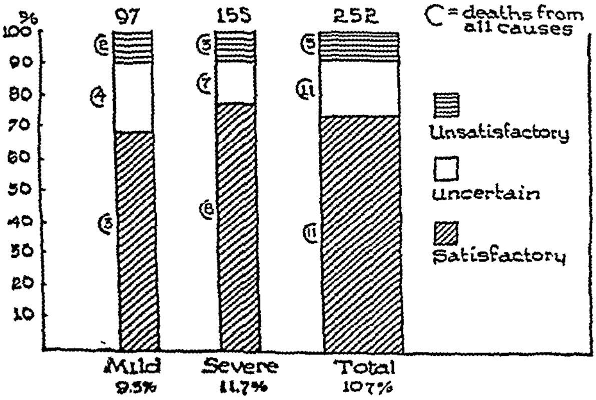

Chart 2.—Outcome by clinical severity at start of treatment in 252 infants.

Almost all the reactions to therapy were febrile in nature. Because of frequent associated infections, it was necessary to define these reactions arbitrarily as follows: febrile, grade I is a rise in temperature of not more than one degree Fahrenheit from the pretreatment level; grade II is a rise of from one to two degrees above pretreatment level, and grade III, any rise over two degrees.

A *satisfactory* outcome signifies the subsidence of observed clinical manifestations in conjunction with negative or progressively declining serologic titer. An *unsatisfactory* result denotes the persistence of reversible manifestations with an unchanged or rising serologic titer or with relapse. The designation *uncertain* indicates that enough time had not elapsed for proper inclusion in one of the other two categories or that legitimate confusion in the interpretation of clinical or serologic results existed. We have defined *serorelapse* as follows: (*a*) if at least two preceding serologic tests were negative over a period of at least one month and then became positive in undiluted serum or in any dilution of serum, confirmed by two subsequent tests of equal or increasing positivity; or (*b*) if the preceding serologic tests were positive in a constant or decreasing titer and then two consecutive serologic tests showed the titer increasing to a value at least four times the point of inflection or two consecutive serologic tests demonstrated a consistent upward trend.

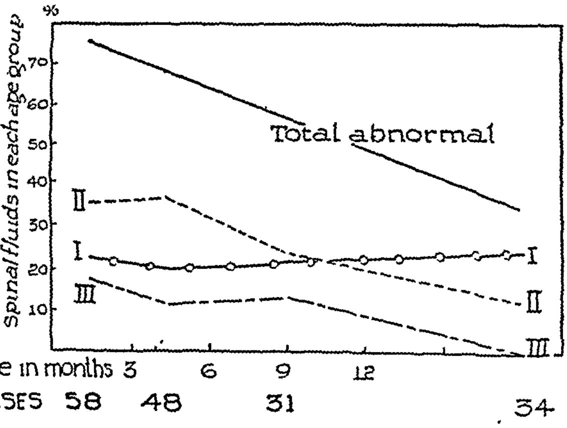

Chart 3.—Type of spinal fluid at start of treatment by age in 171 infants.

Along with appropriate supportive care the infants in this series received total dosages of sodium penicillin varying from 770 to 150,000 units per kilogram of body weight. Among those who completed treatment, the smallest total dosage actually received was 12,000 units. For schedules of 40,000 units or less, the drug was usually administered in aqueous solution, divided into sixty equal intramuscular doses, every three hours over a period of seven and one-half days. For the larger schedules the same plan was followed, but the total dosage was divided into one hundred and twenty equal injections given over a period of fifteen days. Because as much time has not elapsed since these heavier schedules have been used, final comparison of results related to dosage is not yet feasible.

As expected, the majority of "severe" examples of infection (on the grading basis described previously) were encountered in the youngest age groups, the disease of about two thirds of these infants being classed as 2 plus or higher. Among the older infants this situation was almost reversed, the majority of infections now being legitimately characterized as "mild."

---

[2] Moore, J. E.: Personal communication to the authors.

The outcome by age at start of treatment is shown in chart 1. Allowing for varying proportions in the several age groups classified as uncertain (because of inadequate follow-up), there is no significant difference in satisfactory results with age. Apparently poorer results observed in infants treated during the first three months of life compared with those treated in the next trimester probably indicate generally lowered resistance among the youngest infants, or "survival of the fittest" (chart 1). Nineteen of 27 deaths from all causes occurred in infants who were under 3 months of age when treated; undoubtedly the ravages of syphilis, treated or untreated, leave these youngest patients particularly prone to intercurrent diseases. Marginal numerals encircled at the left of each column in charts 1, 2, 6, 7 and 8 refer only to the 27 deaths; a more detailed analysis of these is presented later. The percentage of unsatisfactory results was about equal in mild and severe cases (chart 2). Deaths from all causes have occurred with about equal frequency in mild (9.3 per cent) and severe (11.5 per cent) cases, suggesting that neither severity of infection, as we have graded it, nor penicillin therapy were factors contributing to death.

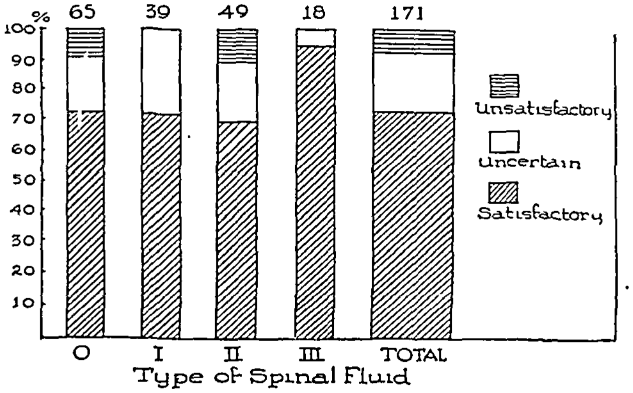

Chart 4.—Outcome by cerebrospinal fluid grade at start of treatment in 171 infants.

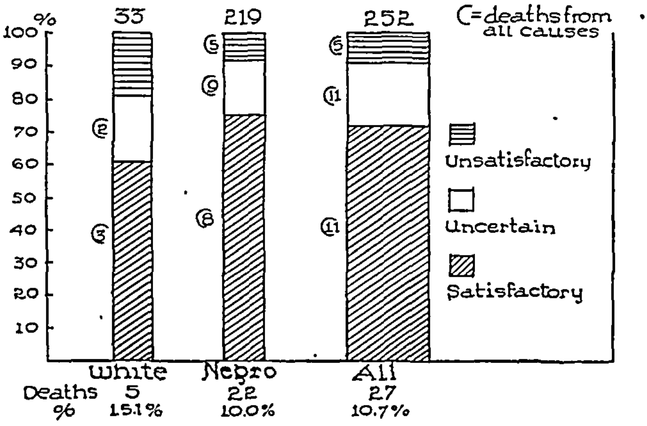

Chart 5.—Congenital syphilis treated with penicillin; outcome by race.

Spinal fluids were examined just prior to the initiation of treatment in 171 infants and were classified according to the usual scheme. In only 65 instances (37.4 per cent) was the fluid considered normal. Type I fluid, i. e., an increase in cells or protein or both, was noted in 39 (22.2 per cent); type III, or the paretic formula, was encountered 18 times (11.1 per cent) and the remaining 49 (29.2 per cent) were found to be intermediate—type II. Among the 106 infants who had cerebrospinal fluid changes attributable to syphilis, there were only 6 examples of clinically recognizable neurologic disorder. Changes in spinal fluid were commonest in younger infants, as noted in chart 3; they were encountered in 76 per cent of fluids from infants under the age of 3 months but in only about 35 per cent of those examined during the second year of life. The proportion having type I fluids remained fairly constant at about 22 per cent, whereas there was a progressive decrease in the number with fluids of types II and III. These data reflect, of course, a tendency for abnormalities of the spinal fluid to disappear spontaneously with the passage of time.

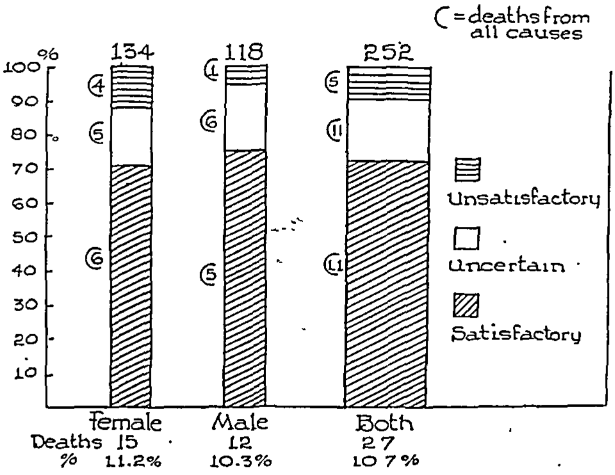

Chart 6.—Congenital syphilis treated with penicillin; outcome by sex.

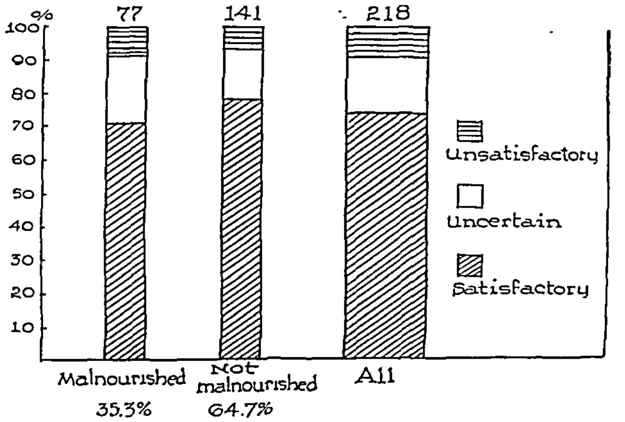

Chart 7.—Outcome by nutritional status at start of treatment (218 infants).

The effect of treatment on these cerebrospinal fluid abnormalities was gratifying (table 1). Although most of the follow-up examinations were made after an interval of about six months, a few were performed too soon after the cessation of treatment for a proper evaluation of results. Early improvement in clinical manifestations of neurosyphilis was encouraging in all but 1 case, but it is of course far too early to make more than a tentative statement in this regard. Among 91 infants, pretreatment abnormalities of the spinal fluid were present in 72.5 per cent, post-treatment, in only 20.9 per cent. To judge from observations made so far (chart 4), little if any prognostic significance can be attached to these abnormalities of the cerebrospinal fluid.

Although only 15 per cent of those treated were white, results were apparently poorer for them than for Negro infants (chart 5); among the latter the results of treatment for a comparatively large number were classed as satisfactory and few as unsatisfactory.

Results appeared to be about the same in boys as in girls (chart 6); no explanation for the questionable difference in outcome by sex can be made. Deaths from all causes occurred with approximately equal frequency in the two sexes.

We have the clinical impression that the nutritional status of the patient when treatment is initiated has some prognostic import, though this hypothesis is not borne out by the data of chart 7. A few more satisfactory and less uncertain or unsatisfactory results were observed in 141 infants who exhibited an apparently normal nutritional state than among 77 infants who were malnourished. It is of interest that only about 35 per cent of these syphilitic babies exhibited recognizable degrees of malnutrition and that such a large majority of this truly representative group of syphilitic infants were considered normal in this respect.

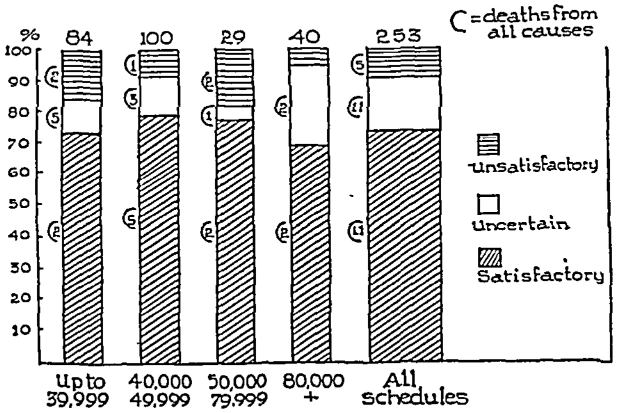

Chart 8.—Outcome by total dosage of sodium penicillin in units per kilogram of body weight.

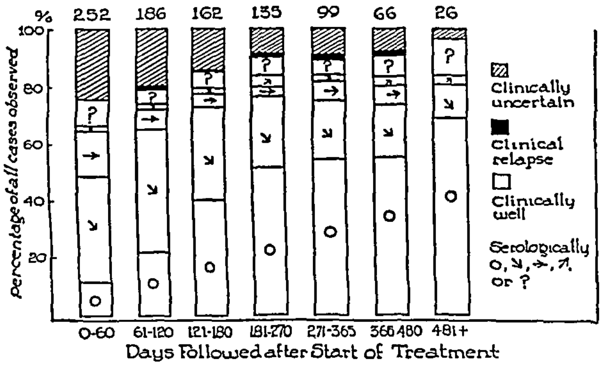

Chart 9.—Status at a specified time after treatment of 252 cases of congenital syphilis; all treatment schedules.

As stated previously, data regarding the outcome of treatment related to the dosage schedules employed are beclouded by at least two important factors: (1) uncertainty as to the actual amount, variety and potency of sodium penicillin administered to any infant and (2) shorter periods of observation for infants treated most recently or with larger amounts of the drug. Expressed ranges were necessary for tabulations because of irregularities in the total dosage given to some infants, though most schedules were calculated to furnish multiples of 20,000 units of sodium penicillin per kilogram of body weight. Among the relatively small number of cases included within any narrow range, wide variations in outcome were observed. Grouping them into larger ranges, as shown in chart 8, one notes that satisfactory results were observed in from 67.5 to 77 per cent. The relatively large number of uncertain results in the group of 40 infants who received 80,000 or more units of the drug per kilogram of body weight is probably due to the fact that they were most recently treated. For all dosage schedules combined, the outcome was satisfactory in about 74 per cent of the cases, unsatisfactory in about 9 per cent and uncertain in approximately 18 per cent. Deaths during or after treatment could not be correlated with the dosage of penicillin used.

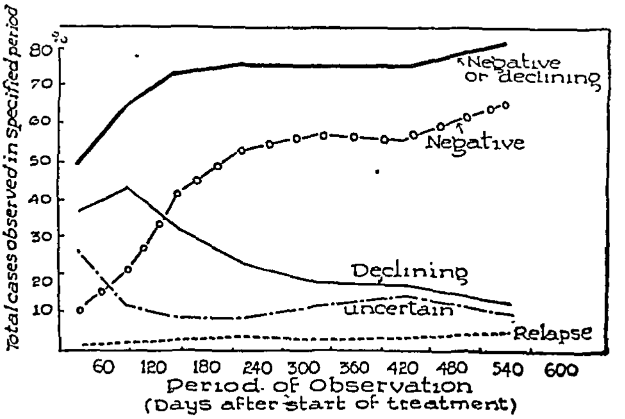

Chart 10.—Serologic status of those clinically well.

If one considers results related to dosage only in cases followed for more than two months, more striking differences are apparent (table 2). After this early interval uncertainties are reduced to a fairly constant level. One notes more satisfactory and fewer unsatisfactory results among infants receiving more than 40,000 units of sodium penicillin per kilogram of body weight.

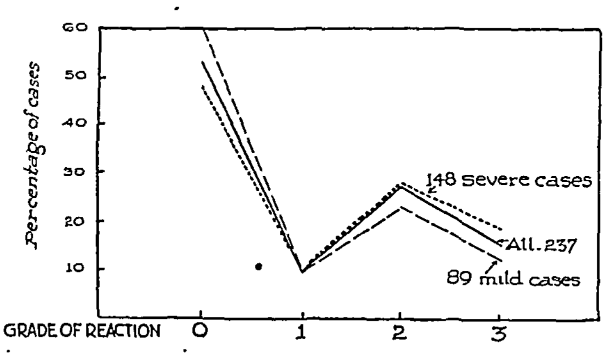

Chart 11.—Febrile reactions during treatment as observed in 237 cases. The grade of reaction is classified as: 1, rise of not more than 1 degree F. from pretreatment level; 2, rise of 1 to 2 degrees F. from pretreatment level, and 3, rise of more than 2 degrees F. from pretreatment level.

Increasingly satisfactory results were noted as time passed after treatment (chart 9). Uncertainties became less frequent. Clinical relapses were distinctly unusual, only 6 (2.4 per cent) being recognized in the entire group. With an increase in the proportion of patients becoming clinically well, there was simultaneous serologic improvement. The percentage of cases in which patients became clinically well and seronegative increased from 11.1 per cent among those observed for less than sixty days up to 69.2 per cent among those followed for more than sixteen months. Most serums became negative between the fourth and twelfth months after treatment, but some were still declining or turning negative even in the last two periods of observation (chart 10). The proportion of stationary, uncertain or rising titers fluctuated relatively little beyond the first two months subsequent to treatment.

Clinical relapse occurred as early as three months and as late as eleven months after initial therapy. Early results of treatment had been considered satisfactory for all 6 examples. The interval between the first rise in serologic titer and evidence of clinical relapse was observed to be as long as seven months in 2 instances. For this reason and because criteria for serologic relapse have been satisfied without subsequent evidences of clinical relapse for as long as eighteen months, we have not consistently retreated infants for serorelapse alone. Clinical relapses have generally been treated with two or more times the original dosage. Results have again become satisfactory in all 6; 1 became seronegative, 5 exhibited a serologic decline, but serorelapse alone recurred in 1 patient after eleven months. Data concerning these patients appear in table 3.

TABLE 1.—*Congenital Syphilis Treated with Penicillin; Changes in Spinal Fluid in 91 Infants*

* Interval of 8 days to 15 months, usually 6 months.
† Reexamined in less than 19 days.

TABLE 2.—*Treatment of Early Congenital Syphilis with Penicillin*

Results in 141 living infants observed from 60 to 480 days after treatment with penicillin.*

Dosage, U/Kg.	Number	Satisfactory	Unsatisfactory	Uncertain
Up to 39,999	66	49 (74.2%)	13 (19.7%)	4 (6.1%)
40,000 or more	75	67 (89.3%)	4 (5.3%)	4 (5.3%)
Total	141	116 (82.2%)	17 (12 1%)	8 (5.6%)

* November 1945.

Aside from the transient febrile reactions to be described, only 10 infants had mild or dubious therapeutic shocks. None were considered severe enough to stop or modify any treatment plan. Over half the patients experienced no reaction. Chart 11 indicates the frequency with which the three grades of febrile reactions were encountered. Reactions of grades II and III occurred a bit oftener in severe cases. From our experience, there is no justification whatever for gradually "building up" the dosage of penicillin in order to avoid reactions.

There were 27 deaths (tables 4 and 5), 9 of which occurred within fourteen days after treatment was started. Among these 9 patients, manifestations of syphilis were known to be improving or healed in 4, had not changed appreciably in 2 and were considered to be worse in 3; serologic titers had decreased in 4 and remained stationary in 1, and tests had not yet been repeated in 4. In regard to syphilis, results of therapy in these 9 patients were considered satisfactory for 2, unsatisfactory for 3 and uncertain for 4. Causes for death other than syphilis were apparent for 8 of these 9 infants, but there was no opportunity to examine the ninth one. Pathologists found anatomic evidences of syphilis in 5, and autopsies were not performed on 3; in 1 case evidences of syphilis were not observed at autopsy. Two of these infants had received only a few injections of penicillin and 1 died on the first day, 1 on the second day of treatment; of the remaining 7, 6 had received 40,000 or more units of penicillin per kilogram of body weight and 1 received less than this amount (23,000 units per kilogram).

TABLE 4.—*Status of Syphilis at Time of Death in 27 of 253 Infants Treated (By Interval to Death)*

Time	Number	Satisfactory	Unsatisfactory	Uncertain
<14 days	9 (3.6%)	2	4	3
14 30 days	8 (3.2%)	2	1	5
>1 mo.	10 (3.9%)	7	..	3
0 6 mo.	27 (10.7%)	11 (41%)	5 (18%)	11(41%)

Of 8 infants who died in the interval between fourteen days and one month after treatment was initiated, clinical manifestations of syphilis were improved or healed in 4, unchanged in 3 and worse in 1. Serologic titers had been repeated for only 4; 2 were declining, 2 unchanged. Results as to syphilis were considered satisfactory for 2 and unsatisfactory for 1 but uncertain for 5. Immediate causes for death other than syphilis were apparent in 6 patients, and 2 could not be examined. Autopsy disclosed evidences of syphilis in 2 children, no evidences of syphilis in 2; the other 4 were not examined pathologically. Of these 8, 5 had received treatment schedules of 40,000 or more units of the drug per kilogram of body weight, and 3 had received less.

Among 10 infants who died from one to six months after treatment was initiated, clinical manifestations of syphilis were healed or improved in all; serologic titers were negative or declining in 7, rising in 2 and equivocal in 1. The effect of treatment on syphilis was judged to be entirely satisfactory for 7, and there had been too few observations for proper evaluation of the results in 3. Causes for death other than syphilis were recognized for all but 2; these died at home, and reliable information could not be obtained. Only 1 autopsy was performed, and this did not reveal evidences of syphilis. The total dosage of penicillin was 40,000 units or more per kilogram of body weight for 7 patients, less than this total amount for 3.

TABLE 5.—*Status of Syphilis at Time of Death in 27 of 253 Infants Treated (By Dosage Schedule Employed)*

	Status of Syphilis			
Dosage, Units/Kg.	Satisfactory	Unsatisfactory	Uncertain	Cases
To 39,999	2	2	5	9
40,000 - 49,999	5	1	3	9
50,000 - 79,999	2	2	1	5
80,000+	2	..	2	4
Total	11	5	11	27

We emphasize that a fatality rate of 10.7 per cent from all causes in this series is slightly lower than that observed among a similar group of infants treated by older plans which employ arsenical compounds and heavy metals.[3]

SUMMARY AND CONCLUSIONS

Among 252 infants with congenital syphilis, a single course of penicillin administered over a period of seven and one-half to fifteen days has yielded satisfactory results in 73 per cent, unsatisfactory in 9.1 per cent; and in 17.9 per cent results are still classed as uncertain. Empirically judged severity of syphilis or cerebrospinal abnormalities had little prognostic meaning; the latter improved remarkably after treatment. Dosage schedules employing more than 40,000 units of the drug per kilogram of body weight yielded better results than those employing lesser amounts. There is some evidence to suggest that larger dosage schedules administered over a longer period of time may be more effective. Dramatic clearing of active manifestations of infection during or *soon after treatment is the rule.* Clinical relapses have been infrequent, with only 6 encountered at intervals of three to eleven months after treatment. As time passes, the number of cases with unsatisfactory or uncertain results diminishes, while there is a proportionate increase in that of symptomatic and serologic cures. Changes to seronegativity are not unusual a year or more after the completion of treatment, though most babies become seronegative between the fourth and twelfth months following therapy.

Judged by outcome, all planned treatment schedules employing sodium penicillin alone have been remarkably effective. Their efficacy, rapidity and safety in this "exquisitely chronic" disease have amply demonstrated that this drug is the best single agent yet employed for the treatment of congenital syphilis.

Penicillin therapy has not altered the familiar contention that treatment of the baby is far more important than treatment of its syphilis. Hazards inherent in socioeconomic environments responsible for a high incidence of this disease undoubtedly account for the high fatality rates seen under any form of treatment. Although syphilis or its direct sequelae must be regarded as potent contributory factors, deaths are almost always adequately explainable on nonsyphilitic bases.

Until the true makeup of commercial penicillin has been clarified or until crystalline fractions are evaluated, we offer the following broad suggestions for therapy:

1. Young syphilitic infants should receive a total dosage of at least 100,000 units per kilogram of body weight.

2. This amount should be divided into approximately one hundred and twenty equal intramuscular injections given over a period of twelve to fifteen days.

3. These injections should be given at intervals of no longer than three hours around the clock.

Table 3.—*Relapses*

Initial Treatment					Result		Relapse		Retreatment		
										Result

N	♀	2 mos.	2+	40,000	Satisfactory	Decline	104 days	328 days	80,000	Satisfactory	Decline

* To second serologic relapse at one year; retreated with 41,000 units of calcium penicillin per kilogram of body weight and remains clinically well but serologically unchanged.

ABSTRACT OF DISCUSSION

Dr. Arild E. Hansen, Galveston, Texas: Dr. Platou has made an excellent presentation and summary of an enormous amount of data. We in the Department of Pediatrics at the University of Texas have been happy to cooperate with him and the other investigators in carrying on these studies. By such cooperative efforts, the solution to the problem may be obtained much earlier and more convincingly. My observations regarding impressions of penicillin in congenital syphilis I owe especially to my colleague Dr. Erle E. Wilkinson, who has been in charge of the syphilis clinic for children in our institution. We have been impressed with the dramatic results reported for the dermatologic manifestations in the small infants, which heretofore were a particular problem because of the nursing care and also the time-consuming and protracted interval necessary in keeping the child under observation. Interesting is the finding that the most satisfactory results occurred in the younger age group. The author has not dealt with the subject in regard to patients with the late manifestations of the disease in whom results do not seem to be so gratifying. In one of our patients suffering with a Clutton's joint, within a week following a course of penicillin there developed a similar involvement of the other knee. A second course of penicillin was given, and five days after its completion interstitial keratitis occurred. In another child treated for bilateral Clutton's joints interstitial keratitis developed following a course of penicillin. Of course, it is well known that interstitial keratitis frequently occurs following the usual antisyphilitic therapy. Of 11 children with interstitial keratitis, 4 appeared to have a favorable clinical response. In the remaining cases either improvement was not noted or the results were difficult to evaluate. In 8 children with late neurosyphilis, a striking clinical improvement was not noted: in 4 there was serologic evidence of benefit. In general, it would appear from preliminary studies that in late congenital syphilis there has been no definite tendency for decrease in the serologic titer, which is in contrast to the decreasing titer in the early congenital syphilis treated with penicillin. It may be that continued observation of patients with early congenital syphilis will lead to a better understanding of the nature of the production of the manifestations of the disease. It will be interesting to follow the small infants and children who have had penicillin early to note the incidence of the development of Hutchinson's teeth. In the overall consideration of the problem, in spite of our dramatic results in the treatment of early cases and the relatively low remission rate, in order to hope to solve the problem unequivocally we must look to the adequate treatment of the mother.

Dr. R. V. Platou, New Orleans: I should like to reiterate the following statements. Until the status of commercial penicillins has been clarified and until our current observations on penicillin G have been further amplified, we recommend a total dosage of not less than 100,000 units per kilogram of body weight of the present commercial penicillins given at intervals of no longer than three hours over a period of not less than fifteen days. All 6 of our patients who had relapses have been retreated with twice the initial dosage of penicillin, and results have so far been satisfactory in each case. I should like to elaborate on the deaths observed in this group of infants. That deaths could not be related to the dosage of penicillin employed or to the severity of syphilis at the beginning of therapy is suggested by the data obtained. As far as response of syphilis to treatment is concerned, there were twice as many satisfactory outcomes as unsatisfactory ones among these deaths. Unfortunately, 11 deaths occurred elsewhere, so that the status of syphilis at the time of death remained uncertain. The status of syphilis could not be significantly related to the time at which death occurred. Among 9 infants who died within two weeks, including 2 who died during treatment, results were considered satisfactory in 2, unsatisfactory in 4 and uncertain in 3. Again, it is notable that among infants dying of all causes subsequent to treatment there were more satisfactory than unsatisfactory results as far as treatment of syphilis was concerned.

DIET LOW IN SALT (SODIUM) IN CONGESTIVE HEART FAILURE

EDWIN O. WHEELER, M.D.
WILLIAM C. BRIDGES, M.D.
and
PAUL D. WHITE, M.D.
Boston

The importance of quantitative restriction of salt, that is, sodium, in the treatment of congestive heart failure has not been generally appreciated, despite the slow accumulation of clinical and laboratory evidence of its place in the control of water balance in the body. With a few notable exceptions, casual limitation of salt and fluid has been the custom throughout the country, and generally more stress has been placed on the restriction of fluid than on that of salt.

Karrell[1] as early as 1866 observed that a diet consisting of 600 to 800 cc. of milk a day often caused diuresis in edematous patients, but he apparently did not realize that the low salt content of such a regimen was largely responsible for its beneficial effects. Physicians have employed this type of therapy successfully down to the present day, generally without appreciating that the restriction of salt rather than of fluid is the important factor. That sodium chloride plays a part in the development of edema was demonstrated by Achard and Loeper[2] in 1901. They fed patients with congestive failure samples of salt and noted that the salt was not excreted in the urine, as it was in normal subjects, and that the blood sodium did not increase. From this they concluded that the ingested salt had contributed to the edema. In 1903 Merklen[3] and Widal and Lemierre[4] used a milk diet in the treatment of edematous cardiac and nephritic patients. Milk was used because of its low salt content, and, as noted by Karrell, an effective diuresis often occurred on this regimen. Widal and Lemierre pointed out that when the intake of salt was kept low their patients could tolerate a large intake of fluid, up to 3 liters a day, without reducing the effectiveness of the treatment.

In spite of these early studies and the later work of many investigators, in particular Gamble,[5] Peters and Van Slyke[6] and Newburgh,[7] which clarified the relationship of electrolyte and fluid balance and clearly demonstrated the fallacy of restricting the intake of water and the importance of restricting that of salt as a means of controlling edema, most physicians continued to treat edematous patients with more stress on fluid than on salt restriction.

The practical application of these principles to the treatment of congestive heart failure awaited the work of Schroeder[8] in 1941. He showed that the restriction of salt was important and that if the intake of salt was held at a low level, the intake of water could be raised to as much as 4 liters a day without causing the formation of edema in patients with congestive failure. Similar investigations have been reported by Schemm,[9] by Proger and his group[10] and by Ellis.[11] The first-named of these workers advocated a very large intake of fluid in addition to a diet low in sodium. In spite of these reports, which indicate the efficacy of salt restriction in the treatment of congestive failure, its application has been neglected.

The signs of congestive failure, such as elevated venous pressure, edema and ascites, have in the past been explained on the basis of back pressure from the failing heart. According to this concept the following series of events occurs: cardiac failure → increased venous pressure → elevated capillary hydrostatic pressure → edema. Recently Warren and Stead[12] have shown that this sequence of events may not be the only explanation. They demonstrated that by feeding salt to the compensated cardiac patient kept at rest in bed evidence of congestive failure can be produced. When this was done, gain in weight and edema preceded rather than followed an increase in the venous pressure. Therefore they postulated the following sequence of events: heart failure → diminished renal excretion of sodium and water → increased blood volume and edema → elevated venous pressure. Neither of these concepts accounts for all the clinical and laboratory observations in congestive heart failure, but the latter explanation does make clear the importance of salt in the formation of edema.

Thus, the use of a diet low in sodium in the treatment of patients with congestive heart failure is based, first,

on the observation that their degree of failure is often directly correlated with their intake of salt and, second, on the modern concepts of the pathologic physiology of the condition.

DETAILS OF THE DIET LOW IN SODIUM

During the last one and a half years we have treated many patients with congestive failure with a diet low in sodium, in addition to the usual measures, such as rest, digitalis and diuretics. In contrast to our former practice, they have been allowed fluids as they desired or, occasionally, have been urged to drink larger amounts, up to 3 liters a day. The diet we have used in the hospital contains about 625 mg. of sodium, or 1.5 Gm. of salt, and 1,800 calories (see the accompanying table). The diet has yielded a neutral ash, though its reaction is probably of little importance, since most of the patients were given ammonium chloride as part of their treatment. In ambulatory office patients the diet has not been so strict, emphasis being placed principally on the elimination of salt from all cooking and the use of salt-free bread and butter.

The comparative amounts of salt (grams per day) contained in diets varying in the degree of salt restriction are as follows: (1) average diet, without salt restriction, 6 to 15 Gm.; (2) average diet, without salt added at table, 4 to 7 Gm.; (3) average diet, without salt added in cooking, 3 to 4 Gm., and (4) low sodium diet, 1.5 to 2.0 Gm. The difference in the salt content of the last two diets is largely due to the use of salt-free bread and butter in the low sodium diet. It is evident that the degree of salt restriction needed depends on the patient's response to treatment, and no doubt some patients are able to tolerate more salt than others.

There are certain precautions which must be carefully observed in following a diet low in sodium:

1. Salt, soda or baking powder should not be used in the cooking or at the table. Substitutes for salt which contain sodium should not be used.

2. Sweet butter or butter that has been washed free of salt may be used. Bread and salad dressings must be prepared salt free. Canned foods, unless prepared salt free, should not be used.

3. Salty appetizers or salted foods, such as nuts, potato chips, sardines, olives, pickles and relishes, are to be guarded against. Cheese and smoked or salted meats are not permitted.

4. Medicines containing sodium should not be used against gas or indigestion. Calcium salts are helpful in this regard.

The advantages of the regimen are threefold:

1. It enables one frequently to control edema which cannot be controlled by the usual measures; that is, by digitalis, moderate salt and fluid restriction, and diuretics.

2. It diminishes the necessity for frequent use of mercurial diuretics or eliminates entirely the need for their use.

3. It enables the patients to take more fluid, eliminates troublesome thirst and insures an adequate intake of fluid to meet the body's demands.

The following disadvantages result from this diet:

1. Some patients find it difficult or impossible to obtain such a diet, especially those who eat their meals in boarding houses or restaurants.

2. Patients almost invariably complain about the flat taste of the food, particularly when they are starting on the diet, and occasionally will reject the regimen because of this.

3. Although it is possible so to deplete a patient by a low sodium intake, especially if repeated mercurial diuretics are being given concurrently, that symptoms of lack of sodium may appear, we have not met with this difficulty in our patients.

Although these objections are occasionally difficult to overcome, they are outweighed by the decided relief that patients often obtain from the distressing symptoms of congestive failure (notably, dyspnea, insomnia and edema) and from the tiring effects of frequent mercurial diureses.

Admittedly, the flat taste of the diet is the greatest single obstacle to its use, and a satisfactory substitute for salt would be helpful when employing this regimen. Although other salts, such as potassium and ammonium chloride are not entirely satisfactory as substitutes, they are helpful when used in small amounts. We are investigating the use of more acceptable substances.

RESULTS

During the last year and a half we have treated 50 patients with congestion due to heart disease of all types with the regimen outlined above. In general, these patients were selected because previous therapy was not satisfactory; that is, dyspnea and edema were not controlled, or mercurial diuretics were used at distressingly frequent intervals. The duration of treatment has varied from one month to one and a half years; seven months has been the average duration. For the most part these patients have been ambulatory and have been obliged to get their diet at home.

Only 4 of the patients were unable to follow the diet satisfactorily. The other 46 patients were able to cooperate and maintain a satisfactory restriction of sodium.

In 11 of the patients the results of therapy with the low sodium regimen could not be evaluated because of many factors, such as surgical procedures, inadequate therapy prior to the onset of the regimen and changes in activity.

Of the remaining 35 patients who faithfully followed the diet, 13 did not show improvement, while 22 were better; of the latter group 10 showed great benefit. In no instances were patients made worse by this therapy. Improvement was judged by the decrease in signs of congestive failure; that is, orthopnea, basal rales, enlargement of the liver, edema, decrease in the need for mercurial diuretics and ability to increase activity.

Eleven of these 35 patients had rheumatic valvular disease, some with active rheumatic fever; of this group only 2 showed improvement which was not pronounced. On the other hand, 20 patients had hypertensive and/or coronary heart disease; of these, 18 showed improvement, in 9 of whom it was pronounced. Of the 4 remaining cases of miscellaneous etiology, 3 patients improved.

ILLUSTRATIVE CASES

The following cases are illustrative of the beneficial effect of a low salt intake in the treatment of patients with congestive failure and edema. The first case (chart 1) illustrates well the considerable diuresis and loss of body sodium which may be induced by a diet low in sodium. For several weeks his congestion had been quite stationary, while he was in the hospital on a diet containing 9 Gm. of sodium chloride. The diuresis was induced by a diet containing 1.7 Gm. of sodium chloride and continued when the salt content of the diet was raised to 4.7 Gm.

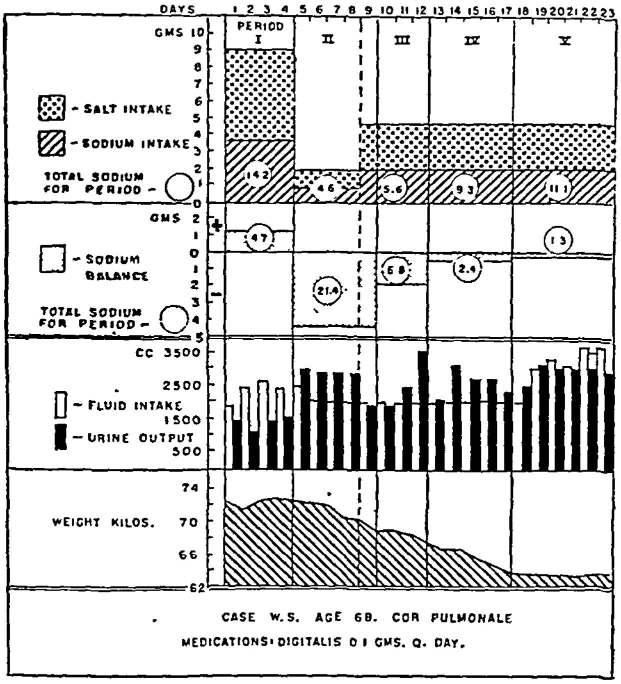

Chart 1.—Diuresis induced by a diet low in sodium, case 1.

The second and third cases (charts 2 and 3) illustate the effect of restricting sodium in 2 ambulatory patients whose obstinate congestion was poorly controlled by the usual means of therapy—regular diet without added salt at the table (a salt content of about 5 Gm.), digitalis, ammonium chloride, and mercurial diuretics consisting of intravenous injections at frequent intervals. In both of these cases the decreased intake of salt was promptly followed by relief from congestion, both pulmonary and peripheral, and from the necessity of using mercurial diuretics. The second of the 3 patients is now living and well, one and a half years after starting the low sodium diet. Being a baker, he has a distinct advantage in being able to prepare his own salt-free bread, a service which he now offers to many of our patients. The third patient resisted the use of the diet for months, because of the flat taste, but after finally agreeing to try it remained free of congestion for three months, until a large myocardial infarct caused his death. These examples demonstrate the usefulness of the low sodium regimen, especially in patients with severe and stubborn congestion.

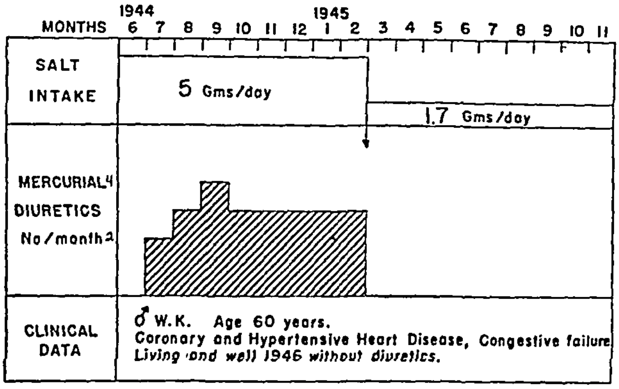

Chart 2.—Effect of sodium restriction in case 2.

COMMENT

The mechanism of the production of edema in heart failure may be dependent on several factors, such as the retention of sodium, increased hydrostatic pressure and, in some cases, a decrease in colloid osmotic pressure due to low serum proteins. Of these various factors, the retention of sodium is one of the most important and at the same time one of the easiest to treat. Since the edema fluid in this condition, like normal extracellular fluid, maintains a constant electrolyte balance with sodium chloride, it is evident that edema fluid cannot be lost without a proportionate decrease in the extracellular salt of the body, the reverse sequence also being true. As long as the intake of salt equals or exceeds the amount of salt excreted, diuresis will not occur.

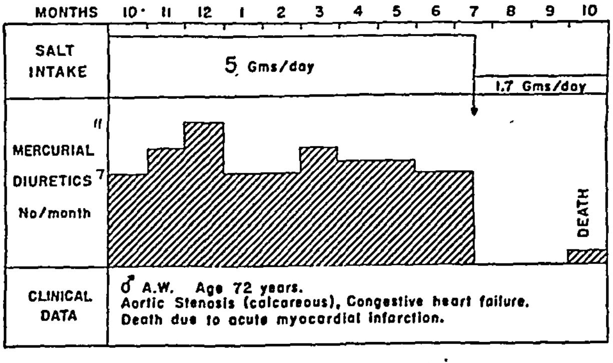

Chart 3.—Effect of sodium restriction in case 3.

Loss of sodium and consequent loss of edema fluid can be brought about either by decreasing the intake or by increasing the excretion of salt. The latter procedure is accomplished by various well known diuretics. The former can usually be achieved by reducing the intake of salt to such levels that the output of sodium will exceed the intake. Our experience, as well as that of others, indicates that a diet containing from 1.7 to 2.0 Gm. of salt will accomplish this in the great majority of patients.

The reason for fluid restriction as practiced in the past is not clear. According to Peters,[6] water acts as a diuretic by increasing the water concentration of the plasma and decreasing the salt concentration, so that the kidneys are stimulated to excrete more than the usual amount of water. An isotonic solution of sodium chloride, on the other hand, does not produce such an effect but is excreted at an exceedingly slow rate. Limitation of fluids can produce dehydration and a consequent slight loss of weight but cannot produce a diuresis. An adequate urinary output cannot be maintained in the presence of great restriction of fluid intake, which is a serious criticism of such therapy. This is especially true in patients with cardiac disease, in whom renal function may already be disturbed.

The optimum intake of water on a diet low in sodium has not been established, but it is evident that patients with congestive failure tolerate comparatively large amounts of fluid without trouble as long as the intake of salt is kept at a low level. Certainly fluid restriction as practiced in the past is wrong, but inasmuch as we have not observed definite benefit from forcing fluids beyond 3 liters a day, and as such an intake is a real trial to the patients, we have allowed them to drink as they wished, advising an intake of at least 2 liters a day.

SUMMARY AND CONCLUSIONS

A diet low in sodium with a liberal intake of fluid has been used, in addition to the usual therapeutic measures, in the treatment of 50 patients with congestive heart failure during the past one and a half years at the Massachusetts General Hospital. Four of these patients were uncooperative, and in 11 the results could not be evaluated. Of the remaining 35, 22 improved. None was made worse. In general, patients with coronary and hypertensive heart disease responded much better than did patients with rheumatic heart disease.

The use of a diet low in sodium in the treatment of congestive failure of the heart is based on sound clinical and experimental ground. Our results and those of others lead us to advocate its more widespread use.

ABSTRACT OF DISCUSSION

Dr. James V. Warren, M.C., A.U.S.: A group in Atlanta, Drs. Stead, Brenner, Merrill and myself, have been interested in the altered circulation in congestive heart failure. Our clinical experience has been the same as that shown by Dr. Wheeler and his associates. The patient is maintained on a low sodium diet and does better; we regard it as an important part of the therapy of chronic congestive heart failure. We all agree that in congestive heart failure there is something wrong with the heart and that the patients may get an elevation of venous pressure and edema. The important point is the interpretation of why they get edema, why they get elevated venous pressure and the relationship between these two phenomena. It is our belief that elevated venous pressure in congestive heart failure may be due to two different factors. In some cases with a very acute decline in cardiac output, the venous pressure may rise precipitously. Such a situation may be seen in patients with pericardial tamponade. It may be seen in patients with acute rapid heart action, paroxysmal tachycardia, for instance. They have abrupt rising of venous pressure. In these patients it is obvious that the venous pressure occurs without any changes in blood value. There is an additional mechanism. In the subjects receiving salt, the venous pressure is presumably elevated by the fact that the blood volume is increased and even after death if one measures the venous pressure, as Starr did, one finds that the static pressure is elevated above normal. There is a second mechanism present, not in acute cardiac failure, but only in chronic cardiac failure. Most patients with chronic cardiac failure, it is our belief, probably have a part of both mechanisms playing a role in the elevation of venous pressure. If one gives digitalis, one may produce abrupt changes in venous pressure. I should like to call attention to a certain group of patients in whom congestive failure has been present and actually treated. With bed rest they are found to have normal venous pressure. If one carefully observes them, even on normal salt intake, they still have an extraordinary avidity for salt; they tend to retain salt to a much greater extent than do normal subjects. Something else, we believe, makes these patients retain salt rather than the elevation of the venous pressure. It can be seen in these patients in the absence of any change in venous pressure. I don't know the answer. Studies by Dr. Merrill and our group have shown an extraordinary diminution in renal blood flow in patients with congestive failure. It may be there is some alteration in renal dynamics which makes for retention of salt and therefore makes these patients develop edema with such great ease. It is our belief that the final answer is not available at present but that it is not a direct result of the increase in venous pressure.

Dr. F. R. Schemm, Great Falls, Mont.: It is good to think that, in spite of conflicting theories about edema, it is possible in edematous patients to overwhelm the effects of a high venous pressure, a low serum protein or an impaired renal excretion of sodium by a relatively simple clinical manipulation of ingested sodium, acid and water and to clear edema and prevent its recurrence more satisfactorily than in the past. This manipulation, which is achieved by the use of a low sodium, neutral or acid ash diet and a liberal fluid intake, seems essential to the clearing of edema in many cases that have not responded to the use of digitalis, mercury, heavy acidification or sharp salt restriction, alone or in combination. Dr. Wheeler reports such results in some of the 35 ambulatory patients whose edema had resisted the customary treatment in Dr. White's service. These patients were given a diet which was no lower in sodium than ours and which yielded the same excess of acid ash, and they received a fluid intake which, while not as high as we often use, was nevertheless from two to three times as great as they were in the habit of using; yet they appear to ascribe their results chiefly to sodium restriction, as did the French investigators fifty years ago. I suspect that the importance of a higher fluid intake in some cases and of the acid ash excess of the diet in others in clearing edema which would not otherwise respond becomes clearly apparent only in a relatively large series of cases of very ill hospitalized patients. Thus, in some 400 observations reported in 1942, and in a similar number not yet reported, I have encountered only 6 per cent that I regarded as perfect controls, whose edema resisted the sharpest sodium restriction and a good excess of acid ash in the diet but cleared promptly when the intake was increased to 5 or 6 liters daily. Similarly, I encountered only 5 per cent of real controls to demonstrate in the same manner the individual importance of the acid ash excess of the diet. My chief difficulties and most dismal failures were not usually encountered in cases of rheumatic heart disease but in cases of advanced degenerative heart disease with a complicating fever or in cases with a nephrotic syndrome; that is, cases in which the vapor loss or renal insufficiency appeared to demand (according to water balance principles) more water than I was able to provide.

Dr. George Burch, New Orleans: The difference between turnover of sodium in normal persons and in those with congestive heart failure is quite remarkable. It is impossible for me to agree that edema develops in patients with congestive heart failure solely because there are differences in the amount of blood that circulates through the kidneys. It must be concerned with more factors than that one. As far as venous pressure is concerned, there is a great deal of discordant relationship between venous pressure levels and the state of congestive heart failure. A patient with congestive heart failure frequently has normal venous pressure values. Patients with congestive heart failure will put out something like a hundredth as much sodium on the same regimen as the normal individual. The use of mercurial diuretics will change that output considerably. Apparently there is something concerned with kidney function and the maintenance of the sodium, a function residing in the tubules, that is of considerable importance in congestive failure. Whether the initiating factor is a change in venous pressure which interferes with kidney function or is a factor due to some hormonal function working indirectly, perhaps, is not known. Certainly congestive heart failure is not a simple process. It is quite complicated, and I would hesitate at this moment to try to settle on one theory or single factor. One can entertain some interesting theories, but the facts are not available to support one or the other. I certainly agree with every one that the restriction of salt is exceedingly important in the management of these patients.

Dr. Frederick M. Allen, New York: This late duplication of my results in heart failure (*J. Metabolic Research* **2**:429, 1922) from Boston, the former opposition stronghold, ignores my original introduction (1920) of the first adequately salt-free diet for hypertension, its adoption by Volhard through two graduate students whom he sent to spend a year in the Physiatric Institute in 1923, the unanimous condemnation in editorials (Salt Intake and Vascular Hypertension, editorial, The Journal, Sept. 29, 1923, p. 1116; The Salt Free Regimen and Vascular Hypertension, ibid., Nov. 16, 1929, p. 1561), in symposiums of the New York Academy of Medicine, and in every review and book by every reputed authority in this country; the recent complete confirmations of my clinical results and animal experiments (*J. Urology* **47**:751, 1942), whereby my small book published in 1925 stands today as the best up-to-date manual of hypertension treatment. The following points were included in a more adequate presentation before the Section on Urology of the American Medical Association on June 11, 1942: 1. During the twenty-five years when I was standing alone against all the professors in all the medical schools of this country, I insisted that the issue was strictly one of accuracy of clinical observation. The final decision should note this point and also my demand (*J. M. Soc. New Jersey* **27**:126, 1930) for a retraction of editorial misstatements. 2. Up to twenty years ago I employed a classification (adopted lately by Kempner and Grollman-Williams-Harrison) of patients refractory to salt-free diet; but my larger subsequent experience offers hope that many such patients under persistent treatment can show more or less improvement instead of the anticipated worsening. 3. The difference between the ease of preventing and the impossibility of curing diabetic gangrene illustrates the principal reason for condemning the authorities and schools for their record of neglecting or mismanaging hypertension throughout its most hopeful early stages, and then after hopeless organic damage has occurred seeking a miracle by medical nostrums or surgical malpractice. The concept (*J. Indiana State M. A.* **18**:445, 1925) that salt-free diet specifically arrests the progressiveness of hypertension signifies that proper early diagnosis and treatment eliminates the candidates for future congestive heart failure, angina, apoplexy and uremia, thus furnishing a rational therapeutic solution of the enormous hypertension problem. Completion of this research would by now have furnished several hundred cases studied for periods up to twenty-five years, to settle this vital point decisively. The oligarchic suppression stands responsible for twenty-five years of unchecked hypertensive disease, which caused more mortality and disability than the World War and altered the course of history through the demise of several presidents and many other leading personalities.

Note.—The discussion by Dr. Allen was submitted to Dr. White and Dr. Arthur Grollman, who comment as follows:

Dr. Paul D. White, Boston: It is a pleasure to acknowledge the observations made years ago by Dr. Allen that salt restriction in the diet of individuals with cardiac weakness and failure (among his hypertensives) was helpful in the control of edema when digitalis alone had not sufficed or indeed even in the absence of digitalis therapy (although digitalis should certainly be prescribed for patients with myocardial failure). We have, however, already expressed appreciation of the still earlier work (by twenty years) of Widal and Lemierre, who demonstrated very clearly back in 1903 that a low salt intake could clear edema without restriction of fluids. I suppose that one of the reasons why these observations of Dr. Allen's did not attract more attention was that the salt restriction was particularly aimed at hypertension. It is of considerable interest that there is now renewed interest in the dietary treatment, including low salt intake, in hypertension. These revivals of interest remind me of the interesting historical development of the general recognition of chronic constrictive pericarditis. Pick in 1896 described pericarditic pseudocirrhosis of the liver due to chronic constrictive pericarditis, following which his name was attached to the condition without the realization that the disease itself and the cause thereof were well described by Chevers of Guy's Hospital in London over fifty years before, that is, in 1842 and were again called attention to quite clearly by Sir Samuel Wilks in 1870. It is too bad that advances in medicine limp along so slowly. A practical result of an interest in medical history might help to prevent such retardation.

Dr. Arthur Grollman, Dallas, Texas: The value of Dr. Allen's comments, although in general true, are detracted from by his vindictive attitude toward those who have failed to accept his conclusions. Ambard at the beginning of this century was actually the first to suggest a low salt diet for hypertension. Dr. Allen's advocacy in 1920 of this procedure was not generally accepted by the profession because of his failure to give a rational or scientific explanation of his claims and his failure to point out certain requirements for applying salt restriction and the limitations of this procedure. Consequently, subsequent workers failed to confirm or adopt his suggestions, not through any malice toward Dr. Allen, as he assumes, but for the reasons cited. The statements in section 3 of Dr. Allen's comments are open, I feel, to the criticism that they represent only his claim and require much more work before meriting general acceptance as proved fact. It is theoretically conceivable that salt restriction, if applied early and continuously, might by reducing the blood pressure prevent certain of the secondary results of this disorder. However, there is no basis for the belief that it is more than a symptomatic procedure and that it will alter the course of the fundamental defect in hypertension any more than it affects the blood pressure in advanced stages of the disorder.

A Joint Enterprise.—*Medicine and nursing are one art, its* aim the care of the patient. If medicine goes on growing, as it must, while nursing is suffering a decline, the achievements of one will be offset by the failures of the other. However sure the diagnosis, neat the operation or apt the drug, the patient dies or suffers if he is badly nursed. Doctors have thus toward the nursing profession a duty of which nowadays they seem hardly aware. In the early days of modern nursing the nurse looked to the doctor for advice and help in developing her specialty, and the results of that collaboration have been an example to the world. Indeed, many of the principles laid down in that atmosphere of confidence and endeavor have stood the test of a century of nursing practice. . . . We believe that the medical profession must take a full and responsible share in restoring nursing to the position in which Florence Nightingale placed it: as an absorbing and stretching career for women with brains as well as satisfying occupation for women who, though not academic, are physically and emotionally apt for the care of the sick. And we think that an important step in this reablement might be achieved by the founding of an experimental school of nursing in which new departures in the curriculum, as well as in the conditions of the nurse's life, might be given a fair trial. A large training hospital might offer the best opportunities for this venture.—*Lancet* **2**:605 (Oct. 26) 1946.

RETROGRADE INTUSSUSCEPTION

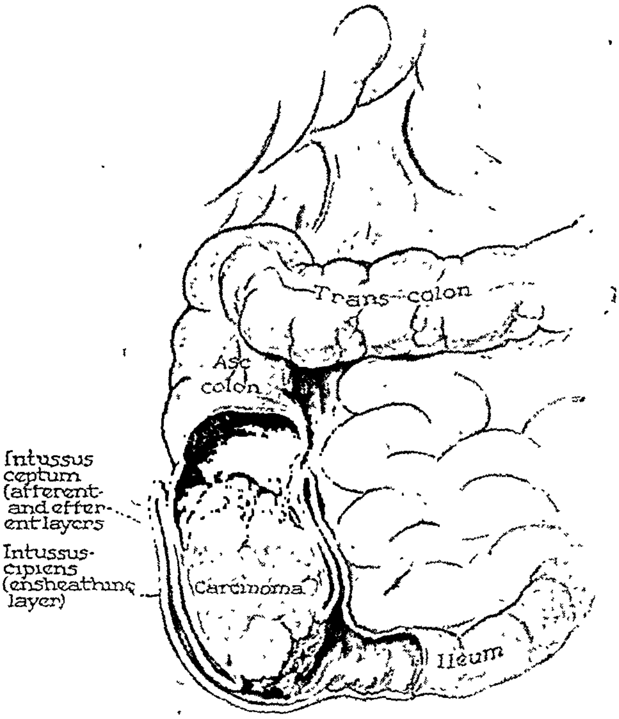
PHILIP THOREK, M.D.
and
W. S. LORIMER, JR., M.D.
Chicago

The clinical picture of an infant suffering the severe agonies of acute intussusception is almost as familiar to the senior medical student as it is to the experienced practitioner. Acute intussusception is the most commonly observed abdominal emergency in children under 2 years of age. Usually swollen Peyer's patches, gastroenteritis, Meckel's diverticulum or a faulty diet cause one part of the intestinal tract to invaginate into an adjoining portion. The mechanics of this process are not difficult to understand, since we know that the presence of material within the lumen of the normal intestine stimulates peristalsis, be it edematous mucosa, succus entericus, a tumor mass or a filled balloon. The hyperperistalsis thus stimulated forces the contents onward, and if the contents consist of a portion of the wall of the intestine, isoperistaltic intussusception results. If by vigorous peristalsis the intestine is unable to pass its contents distally, it reverses its direction, and the contents are forced in the opposite direction. This protective phenomenon occurs when a portion of the gastrointestinal tract is overstimulated by chemical irritation, inflammation, mechanical obstruction or neuropathologic states, both central and peripheral. According to Alvarez's[1] metabolic gradient theory, the fundamental factor which determines the polarity of intestinal peristalsis is the metabolic activity of the intestinal muscle. The normal metabolic rate progressively diminishes distally from the duodenum along the intestinal tract to the rectum. Thus in the presence of inflammation in one portion of the intestinal tract, the metabolic rate of this portion increases and when it exceeds that of a more proximal portion, it becomes the center of polarity. This process is comparable to the irritable focus sometimes found in the diseased myocardium which affects its rhythm.

Antiperistalsis can be as efficient in ridding the intestine of its contents as normal peristalsis, and, like the normal, its force increases progressively as long as the etiologic factor is present or until the intestine becomes exhausted. Antiperistalsis occurs in all portions of the gastrointestinal tract. It occurs in the normal process of digestion in the duodenum below the cap and also for a variable distance above the ileocecal valve to check the rapid passage of ileal contents into the cecum. By full appreciation of efficient antiperistalsis we can understand how intussusception in reverse, or retrograde intussusception, may occur.

In the classic type of intussusception the invaginated loop consists of two layers, an afferent and an efferent, these two forming the intussusceptum. The distal loop forms a single ensheathing layer and is called the intussuscipiens. *In our case of retrograde intussusception,* however, the afferent layer consisted of large bowel and the efferent, of small bowel; the two layers formed the intussusceptum. The ensheathing layer, or intussuscipiens, consisted of small bowel (see the accompanying illustration).

An accepted anatomic classification of intussusception is as follows: (1) *enteric,* in which small intestine invaginates a portion of itself; (2) colic, in which a portion of the large bowel intussuscepts into a more distal portion, and (3) enterocolic, in which small intestine telescopes into cecum and colon. According to Maingot[2] the enterocolic type accounts for approximately 85 per cent of all cases of intussusception. This is clearly understandable when one considers the relatively small diameter and mobility of the ileum compared to the larger and more stable cecum and ascending colon. We wish to add to this classification: (4) retrograde intussusception, in which any of the foregoing may be reversed. Groper[3] has suggested a classification for retrograde intussusception as follows: (1) *jejunogastric,* the jejunum prolapsing through a gastrojejunostomy stoma; (2) enteric; (3) ceco-ileal, the cecum prolapsing into the terminal ileum, and (4) colic, any portion of the large bowel invaginating a more proximal part.



Trans-colon
Asc colon
Intussusceptum (afferent and efferent layers)
Intussuscipiens (ensheathing layer)
Carcinoma
Ileum

Retrograde intussusception caused by an adenocarcinoma of the cecum. The afferent layer consists of large bowel and the efferent of small bowel. The ensheathing layer is made up of small bowel.

REPORT OF A CASE

C. G., a Negro woman aged 59, entered Cook County Hospital Sept. 1, 1945, the second time in two months, complaining of diffuse abdominal pains.

On previous entry in July, 1945, roentgenologic examination revealed distention of the small bowel, and a qualitative Benedict's test revealed sugar in the urine. The patient responded to duodenal decompression and the ingestion of a basic diabetic diet; ten days later she was discharged asymptomatic.

Symptoms recurred shortly after her return home, however. Typical attacks consisted of diffuse, intermittent colic occurring every twenty-five to thirty minutes, lasting about five minutes; it began slowly, reached a peak of intensity and then slowly

[3] Groper, M. J.: Ann. Surg. **112:** 344 (Sept.) 1940.

subsided. The pains were accompanied with anorexia, nausea and constipation. After a day and night of these symptoms, she noted abdominal distention and frequent copious vomiting which continued for from eight to ten hours. A watery, profuse diarrhea followed the vomiting, and the patient was then completely free of symptoms, only to have a recurrence of this syndrome three or four days later.

These episodes had been present for five months, and since their onset the patient's weight had dropped from 165 to 135 pounds (75 to 61 Kg.).

Persistence of these symptoms prompted her to reenter the hospital Sept. 1, 1945, six weeks after her previous discharge. At this time she was having a typical episode of diffuse pains, distention, feculent vomiting and obstipation. A review of the system for symptoms and past and family history were noncontributory. She did not have a history compatible with a previous intraperitoneal inflammatory condition or previous operation.

Physical examination at this time revealed a dehydrated, well preserved Negro woman, completely relaxed between apparently severe episodes of abdominal cramping. The temperature was 99.8 F. per rectum; the pulse rate was 90; the respiratory rate was 20 and the blood pressure was 108 systolic and 80 diastolic. On abdominal examination, inspection did not reveal scars or external hernias. Diffuse distention above the xiphopubic plane was present, and visible and audible peristalsis was observed in the hypogastrium concomitant with the painful seizures. Rigidity was not present, and there was a minimal amount of tenderness on deep palpation in the right paraumbilical region. Masses or organs were not palpated. Peristaltic sounds occurred about one each minute as high-pitched tinkles, replaced every ten to fifteen minutes by loud rushes. The rectum was empty, and masses were not palpable. Pelvic examination revealed a small, freely movable uterus without evidence of previous pelvic inflammatory disease. The red blood cell count was 2.98 million, the hemoglobin 58 per cent and the white blood cell count 13,400. Urinalysis was normal except for a trace of sugar. A scout film of the abdomen revealed distention of the small bowel without gas in the colon. The patient took and expelled a diagnostic enema of 2 quarts of tap water. The report on the barium enema revealed "complete and rapid filling of the entire colon with no evidence of filling defects seen." The total protein determination was 6.0 Gm. per hundred cubic centimeters. The carbon dioxide combining power was 56 per cent (the normal, 50 to 70 per cent). The blood sugar was 180 mg. per hundred cubic centimeters. Duodenal suction decompression resulted in complete relief of the patient's symptoms within twenty-four hours, and she passed large amounts of watery, brown stool, which tested 4 plus to benzidene for blood. Suction was discontinued, and a few days later the patient was given a half-cup of a thin mixture of barium by mouth. The stomach and duodenum were normal. In six hours the barium had filled a greatly dilated loop of the small bowel in the lower left quadrant.

The patient was adequately prepared within two weeks for abdominal laparotomy. Through a left pararectus incision, a mass the size of an orange was found in the right lower quadrant. This mass was between the distal end of a dilated hypertrophied loop of ileum and the proximal end of the transverse colon. The terminal ileum into which this cecal mass had invaginated was shaped much like a bell. The cecum, appendix and ascending colon could not be identified as such. A right hemicolectomy after the Lahey modification of the Mikulicz operation was performed. The patient made an uneventful recovery. The spur was successfully crushed with a Wertheim clamp two weeks postoperatively, and the colostomy was closed two months later. The patient is asymptomatic and has gained 10 pounds (4.5 Kg.) since her operation. She states that she feels better than she has felt in several years.

The diameter of the terminal ileum was one and a half times that of the transverse colon, and the wall of the ileum was hypertrophied and thicker than any portion of the large bowel. On opening the specimen one could see a proliferating tumor infiltrating indurated mucosal folds and fixing them into one contiguous mass. There was a small lumen comparable to that seen in the recanalization of a vascular thrombus. A probe could be passed through this lumen. The pathologist reported an adenocarcinoma of the cecum.

COMMENT

Pathologic Physiology.—In this case the reverse of the relatively common enterocolic intussusception occurred. The smaller cecum and ascending colon invaginated into the larger ileum. Just as the normal difference in the diameters of the ileum and the cecum is a predisposing factor in the enterocolic intussusception, the reverse of this anatomic relationship was a predisposing factor when the cecum invaginated into the ileum as in the case here described. The proliferating adenocarcinoma was the etiologic factor, and the pathologically dilated ileum and collapsed colon served as predisposing causes. The hypertrophied terminal ileum at the site of the inflammatory mechanical obstruction assumed the polarity of peristalsis, and a forceful antiperistalsis occurred. The tumor mass obstructed the cecum and ileocecal valve, and by contiguity the appendix and ascending colon were included in the mass. This entire segment was then caught in the forceful antiperistaltic waves of the dilated hypertrophied terminal ileum, and retrograde intussusception was the result.

Goodyear [4] reported a case similar to this with retrograde intussusception of the cecum into the terminal ileum.

Enteric.—Catz [5] described a case in his practice in which diagnosis was difficult because of the good general condition of the child (4 years old) who had suffered only slight pain, had vomited infrequently and had not passed blood per rectum. Palpation in the lower umbilical region revealed a mobile mass. Operation was delayed for the removal of an enormous fecal mass by oil lavage. However, the pulse rate had risen from 90 to 120, and a laparotomy was performed. A tense black mass was found which on examination proved to be a loop of small intestine about 20 cm. long, curving on itself and forming a closed circle, as it were, attached to a pedicle. At the narrow pedicle the loop was twisted. In the course of detorsion a slightly distended loop of small intestine about 50 cm. proximal to the cecum turned back sharply at a point where torsion was applied and lost itself in the portion of small intestine immediately above. The sheath was manifestly gangrenous. The loop was resected, and end to end anastomosis was in progress when the child vomited a flood of black liquid, which partially asphyxiated it. Death followed eight hours after the operation.

Cioffi [6] reported a retrograde intussusception involving the small intestine due to a Meckel's diverticulum. Caminiti [7] reported one due to an angioadenoma, and Buckley's [8] operation on a child 2 years of age showed a superimposition of a retrograde intussusception on an isoperistaltic one of the small intestine. Groper [3] described a case in which a retrograde intussusception of the ileum into the ileum and jejunum was complicated by volvulus at the site of the intussusception. Neither could be reduced because of the extensive edema of bowel and mesentery, and resection was necessary. Seven and one-half feet (228.6 cm.) of jejunum and ileum were resected, and a side to side anastomosis was performed. The patient made an uneventful recovery. The similarity of this case to that of Catz's is noteworthy. Mitchell's[9] patient made an uneventful recovery after a lateral anastomosis following resection of a gangrenous, retrograde intussusception involving about a foot (33 cm.) of terminal ileum.

[8] Buckley, J. P.: Brit. M. J. **2**: 665 (Nov. 22) 1919.

Colocolic.—Balfour[10] actually had an opportunity to observe the mechanism of retrograde intussusception at the operating table. In an operation for obstruction due to a tumor of the sigmoid he saw that there was a retrograde intussusception of the sigmoid into the descending colon. He reduced it, but as he was watching the area strong antiperistaltic activity set in, and it invaginated itself again.

Flemming[11] successfully operated on an intussusception of the descending colon into the transverse colon. The etiologic factor in his case was a benign tumor. Lewis[12] and Schoenfeld[13] have also reported cases of retrograde colocolic intussusception.

Multiple.—As mentioned previously in Buckley's[8] case, superimposition of retrograde intussusception on a direct one may occur. Catz[5] listed a number of cases of primary intussusceptions; cases in which progressive and retrograde intussusception occur on two separate intestinal loops, and cases in which two invaginations meet head on. In a case observed by Sainet,[14] the descending invagination telescoped the retrograde intussusception. In one observed by Knaggs,[15] the telescoping was the reverse. Moutard-Martin[16] noted a retrograde intussusception of the descending and transverse colon into the cecum; the whole mass so formed penetrated the descending colon, pulling a part of the small intestine with it. D'Arcy Powers[17] reported an identical case.

Jejunogastric.—Groper,[3] McNamara,[18] Shackman,[19] Chamberlin[20] and many others have reported retrograde intussusceptions of the jejunum through the gastrojejunostomy stoma. However, it seems likely that this process is not explainable on the same basis as are the enteric ceco-ileal and colocolic varieties. In all but the gastrojejunal type vigorous antiperistalsis is a necessary factor and as a general rule occurs in the presence of an intrinsic tumor mass which has caused an obstruction, either complete or partial. It is usually aided by decided differences in the diameters of the adjoining segments of bowel involved as was noted in our case.

CONCLUSION

An unusual condition of retrograde intussusception (large bowel into small) resulted from a chronic intestinal obstruction of the terminal ileum which was produced by a carcinoma of the cecum.

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
CHICAGO

(Continued from page 1070)

(Note.—*Following is the ninth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of The Journal. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in The Journal. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—Ed.)

CHAPTER 9. *Medical Progress*

The years from 1859 to 1863 provided a short but significant list of steps in permanent medical advancement in the United States and in the world as a whole. The discovery by Pasteur of anaerobic bacteria, the mapping by Broca of the speech center in the brain, Raynaud's description of symmetric gangrene and Pasteur's detection of silk worm disease were first steps toward a sudden flowering of medical knowledge. There was no single great discovery, like anesthesia, to seize the imagination of all the world. The Civil War, which swept the United States from 1861 to 1865, was a damper on research.

The year 1865 saw the publication of Mendel's memoir on plants. In 1866 Voit established the first hygienic laboratory in Munich and Graefe described sympathetic ophthalmia. The first International Medical Congress was held at Paris in 1867 and the *American Journal of Obstetrics* was founded in the United States in 1869.

Indeed all the years up to 1876 were years of slow progress. J. Marion Sims had published his notes on uterine surgery; Esmarch introduced his first-aid bandage. There were more studies on localization of areas in the brain. Laryngology began to be demarcated as a specialty, and a laryngologic society was established in New York. As early as 1874, Paul Ehrlich introduced dried blood serums and introduced staining methods for blood cells and other tissues of the body. The name of Weir Mitchell did not appear among those interested in the American Medical Association but he had introduced his rest cure in 1875. Great Britain passed a public health act and the English Food Adulteration act in the same year, which marked also the founding of the Boston Medical Library. In fact, the year which marked the centennial of freedom in the United States also saw the founding of Johns Hopkins University and the introduction of the telephone. What would medical practice be like today without the telephone?

THE POSTWAR YEARS—1865-1869

1865

BOSTON

The meeting of 1865 resulted in the introduction and adoption of a resolution which has had a profound effect on the quality of medical literature in the United States. Each year since then it has been sent to every physician who obtains a place on the program of the Annual Session of the American Medical Association. The resolution is a guide to the executive committees of the individual Sections of the Association in recommending papers to the Editor of THE JOURNAL. The resolution, introduced by Dr. Robert Burns, reads:

> "*Resolved,* That the several Sections of this Association be requested, in the future, to refer no papers or reports to the Committee of Publication, except such as can be fairly classed under one of the three following heads, viz: 1st. Such as may contain and establish *positively* new facts, modes of practice, or principles of real value. 2d. Such as may contain the results of well-devised original, experimental researches. 3d. Such as present so complete a review of the facts on any particular subject as to enable the writer to deduce therefrom legitimate conclusions of importance.
>
> "*Resolved,* That the several Sections be requested, in the future, to refer all such papers as may be presented to them for examination by this Association, that contain matter of more or less value, and yet cannot be fairly ranked under either of the heads mentioned in the foregoing resolution, back to their authors with the recommendation that they be published in such regular medical periodicals as said authors may select, with the privilege of placing at the head of such papers, 'Read to the Section of the American Medical Association on the day of 18 .'"

The Association had become active in establishing ethical considerations, particularly as related to advertising and promotion of individual physicians in the public press. Several physicians had been dropped from their local medical societies. The House of Delegates of the American Medical Association had confirmed their expulsion. At a previous session a resolution was introduced affecting Dr. Montrose A. Pallen. It was alleged that he had imperiled the lives of thousands of people in the city of New York by participating in a plot to poison the Croton reservoir by which the city is supplied with drinking water. The action followed the report of a military committee in Washington. Now a distinguished group, including more than thirty-five of the leading physicians of America, protested the previous action and asserted that the guilt of Dr. Pallen had never been established. The resolution was referred to a committee, which pointed out that this was the first time that a group before the Association had protested an action of the majority. They suggested that the evidence indicated that Dr. Montrose A. Pallen had left St. Louis early in the war in the interests of the rebellion and that the testimony pointed toward his complicity in the attempt to poison the water in the Croton reservoir. After this report was read, a telegram came from Dr. Pallen charging that the man who had testified against him had been proved the perpetrator of an infamous perjury. With this confusion of data before the meeting, the resolution was *laid on* the table. The following year when the committee to which the matter had been referred found that the statements on which his expulsion was based were entirely unfounded, Dr. Pallen was restored to membership. He expressed himself highly gratified by the action of the Association and thanked the members.

PRESIDENTIAL ADDRESS OF NATHAN SMITH DAVIS

Notable among the presidential addresses that had been delivered to the American Medical Association was the address by Nathan Smith Davis in 1865. He expressed the congratulations of all on the fact that the United States were again united. "The climax of human wickedness," he said, "had been reached" in the murder of the Chief Magistrate. The year had witnessed the death, too, of Drs. Jonathan Knight of New Haven, Conn., and Valentine Mott of New York.

Twenty years had passed since the first call for the formation of the American Medical Association. Dr. Davis was greatly disappointed that the meetings were now so taken up with events that proper consideration was not being given to some of the most significant interests. He said, "Whenever medical education became the theme of discussion, those more interested in the reading and discussion of papers and reports of a direct scientific and practical character were ever ready to restrict debate, refer the subject to committees or in some other way avoid what they regarded as a mere waste of time. On the other hand, if the reading of an elaborate scientific paper was commenced the author would seldom complete the first half dozen pages before the zealous advocate of educational reform would dispose of the whole subject by a motion to dispense with further reading and to refer the document directly to the Committee of Publication." The good natured lovers of good dinners and sight-seeing would always be ready to aid the other parties with their votes and to secure the acceptance of every invitation to an entertainment, an excursion or a public institution.

During the years all sorts of attempts had been made to control these difficulties by modifying the Constitution or the By-Laws. Standing committees had been abolished and committees on special subjects substituted. Papers requiring more than ten pages of manuscript were compelled to be presented in abstract, and the Committee on Arrangements had been instructed to check the evils of extravagant and costly entertainments by omitting all such from the program of arrangements.

None of these reforms had been satisfactory. "The attempt to eliminate from the program the entertainments," he said, "has resulted only in exchanging one magnificent public banquet occupying one evening for three or four private ones during the annual sessions of the Association." The Association was being criticized because its annual meetings partook more of the character of gourmandizing and sight-seeing than of grave, professional and scientific inquiry.

Nevertheless the Association had made great progress in its fundamental effort to improve medical education. Dr. Davis, therefore, proposed a plan relative to entertainments, which has been followed since that time by the American Medical Association. It is well to read the proposal in his own words:

> But the arrangements for that evening should be such as would permit the most free and cordial intercourse. A public hall should be provided in which gentlemen and ladies could mingle and promenade freely; where each could seek out his old friends and make the acquaintance of new ones; where wit, repartee, and, if need be, songs, sentiments, and speeches could be made to enliven the evening. A simple stand might be placed in some corner, where all who wished could obtain a dish of ice cream, strawberries or other fruit, and a cup of coffee. But there should be neither ostentatious show, nor rich viands, nor strong drinks, for the acknowledged guardians of the public health should not, especially in their highest representative capacity, themselves publicly violate the plainest laws of hygiene.

This farsighted man made other proposals which have been effective. He recommended that each Section be authorized to choose its own officers who should prevail for a year; that each Section adopt well considered rules to govern the reading, discussion and final disposition of all reports, papers and questions that came before it; he suggested that each Section be provided with either a skilful secretary or a professional reporter who would provide a summary of all discussions on scientific questions and papers. He pointed out that results can "never be accomplished by any amount, either of good *wishes* or *fault-finding;* but by prompt, persevering, disinterested action."

1866

BALTIMORE

The first distinguished guest to appear at the meeting of the American Medical Association attended the meeting in 1866 and gave an address. He was Dr. Brown-Séquard, founder of our science of endocrinology and renowned throughout the world for his magnificent contributions in this field.

This year was notable for the majority and minority reports of the Committee on Medical Ethics dealing with specialization. The majority report listed the advantages of specialization as including minuteness in observation, acuteness in study, wideness of observation, skill in diagnosis, multiplicity of invention and superior skill in manipulation. The disadvantages were a narrowness of view, a tendency to magnify unduly the diseases which the specialty covers, a tendency to undervalue the treatment of special diseases by general practitioners, some temptation to the employment of undue measures for gaining a popular reputation and a tendency to increased fees. The advantages far outweighed the disadvantages from the point of view of the patient and of the advancement of the specialty. The committee felt that these disadvantages could be overcome if the specialist would begin as a general practitioner and gradually grow into his specialty.

The committee was especially concerned with the means by which the specialist made himself known to the community. They felt that there should be no advertising either in newspapers or medical journals.

The minority report was signed by Dr. Henry J. Bowditch. He considered that the whole tendency of modern science was toward specialism but he felt also that the Association had no business passing on the question of the advertisements unless they were evidently of a mountebank character. It was his opinion that "any Association would be better occupied in the hearing of able papers and in discussions on all subjects connected with medicine than in any movements for the mere discipline of erring members."

When these reports had been presented to the delegates they were referred to the Committee on Publication, and a motion introduced by Dr. J. Solis-Cohen of Philadelphia which suggested that these be a special order of business at the meeting in 1867 was adopted.

1867

CINCINNATI

Although N. S. Davis had remonstrated against entertainments on too lavish a scale in 1866, the convention which met in Cincinnati in 1867 had a mighty good time. The program lists a half dozen private receptions, a public reception by the physicians of Cincinnati, a steamboat excursion at the expense of the City Council, an exhibition of steam fire engines by the chief of the Fire Department, a little reception for the delegates on the closing day by the proprietors of Longworth's Wine House and an excursion to the Longview Lunatic Asylum.

There were the usual resolutions on the advancement of medical education and on the rank of medical men in the Army and Navy, with the conclusion that a committee should see the President of the United States and the Secretary of the Navy to urge adoption of the changes recommended.

Dr. Allen March of Cincinnati had been able to collect photographs of all the Presidents of the Association and it was moved that they be consigned to the archives.

As a result of action taken in a previous meeting, the delegates from the medical colleges of the country had been assembled in Cincinnati and had adopted certain principles of standardization which the American Medical Association now approved. The Association of American Medical Colleges and the Council on Medical Education now cooperate closely in maintaining standards. Again the American Medical Association urged the states to set up licensure for physicians, but a resolution asking members of the medical profession not to patronize druggists who manufactured nostrums was rejected.

At this early date there were already medical politicos who thought a great deal would be gained in the way of prestige for the American Medical Association if it could only have close contact with Washington. Indeed this argument convinced even N. S. Davis, so he offered a resolution suggesting that the next Annual Session of the American Medical Association be held in the city of Washington and that it be held there every second year thereafter. Still on the somewhat teetotalitarian and puritanic side, his resolution also suggested that whenever the Association met in Washington the Committee on Arrangements be strictly forbidden either to provide themselves or accept provision by others of any entertainment or excursion whatever. With due caution the convention amended this resolution, adopting it except that the meeting should be held in Washington until otherwise ordered and that entertainments or excursions were forbidden if they conflicted with the regular business of the body or its sections.

From Pennsylvania came a resolution urging the members of the faculty of the University of Pennsylvania and the Jefferson Medical College to join their county medical societies and participate with the rest of the medical profession in the work of the American Medical Association.

Dr. G. C. Cox, who had attended a meeting of the British Medical Association as the first delegate from the American Medical Association, indicated that he had been most graciously received by our British colleagues.

1868

WASHINGTON, D. C.

The meeting in Washington, D. C., was marked by visits to the President, the Chief Justice, the Speaker of the House of Representatives, the Army Medical Museum and the Mayor of Washington—each of whom gave receptions for the delegates. Furthermore, on Thursday night, May 7, the Capitol was lighted and the dome illuminated from 8 until 9 p. m. These multitudinous political receptions apparently minimized other features of the convention, for the volume of *Transactions* of that year is the slimmest of its generation.

The Committee on Medical Ethics had a report signed by Dr. H. I. Bowditch alone. The *Transactions* state simply:

> Dr. Bowditch had become chairman by the death of two of his colleagues. He had been unable to elicit any replies from his two other colleagues, and therefore was compelled to act in his individual capacity.

For the first time the bitter and burning question of women doctors came to the fore. Dr. Bowditch strongly advocated the recognition of regularly educated and otherwise well qualified female physicians. This resolution was made a special order of business.

As the meeting was in Washington, Senator Drake of Missouri, who visited the convention, was invited to a seat on the platform and entertained the Association with some remarks in allusion to his connection with the medical art through his father, the late Prof. Daniel Drake.

When the resolution on women doctors came to consideration, it was discussed at some length and then consideration was indefinitely postponed.

As evidence that the bitter feelings of the war had been dissipated, the Association elected as President Dr. William O. Baldwin of Alabama, who made a beautiful address in behalf of the Southern physicians. Among his concluding paragraphs was the following inspiring statement:

> For myself, and for those whom I represent, I grasp with unaffected pleasure the hand which you have so gracefully and magnanimously offered, and I hope and believe this sentiment will meet a ready response from all our brethren of the South. *Let us again be united as friends and brothers.* Ignoring past and present political differences, let us exhibit to this distracted country an example of forgiveness and toleration worthy of the emulation of a great and noble people. Let the bonds which we acknowledge here bind us in all portions of this broad land as a sacred brotherhood, engaged in a common toil, with one mind, one heart, and one purpose. Let the place annually selected for our meetings be our Mecca. There let us meet with harmony of sentiment for thorough organization, for connected and concerted action, without which no great science or art can ever attain its highest perfection. Exacting from each other only the qualifications necessary for honorable membership, let us there mingle in the sacred precincts of our humane profession, and join hands and sympathies in the strengthening influences of association and fellowship; and as we lay fresh offerings in the temple of a noble science, and build new fires on her altars, let us cherish in our hearts the ennobling sentiment of brotherly love.

Again at this meeting in Washington, the Association heard a word of praise from a President who was among the greatest of the leaders of American medicine in this country. Dr. Samuel D. Gross, who had been associated with teaching in medical schools in Louisville and in Philadelphia, urged particularly the establishment of suitable training for nurses. He said:

> I am not aware that the education of nurses has received any attention from this body; a circumstance the more surprising when we consider the great importance of the subject. It seems to me to be just as necessary to have well-trained, well-instructed nurses as to have intelligent and skilful physicians. I have long been of the opinion that there ought to be, in all the principal towns and cities of the Union, institutions for the education of men and women whose duty it is to take care of the sick, and to carry out the injunctions of the medical attendant. There is hardly one nurse, of either sex, in twenty who has a perfect appreciation of the requirements of the sick-room, or who is capable of affording the aid and comfort so necessary to a patient when oppressed by disease or injury. It does not matter what may be the skill of the medical practitioner, how assiduous or faithful he may be in the discharge of his functions, as a guardian of health and life, his efforts can be of comparatively little avail unless they are seconded by an intelligent and devoted nurse. We need in this country a million of Florence Nightingales, and at least half that number of John Howards, to aid our physicians in their strife with disease and death. Myriads of human beings perish annually, in the socalled civilized world, for the want of good nursing.

The committee which reported on the recommendations and suggestions contained in the President's address recommended the adoption of a resolution which would set forth the views of the President regarding the education of nurses and strongly recommended the establishment in all of our large cities of training schools for nurses.

1869

NEW ORLEANS

Still further demonstrating the desire for complete *rapprochement* with the Southern contingent, the convention of 1869 met in New Orleans, where they were warmly greeted by the full attendance of the Southern physicians.

At this time an Association of American Medical Editors was formed. The president, Dr. William O. Baldwin, struck a forlorn note as he viewed the accomplishments in relationship to medical education. He said:

> The plan of action you have adopted, that of endeavoring to induce forty or fifty medical colleges, with conflicting interests, to agree voluntarily upon a "uniform and elevated standard of requirements for the degree of M.D.," and adopt it in good faith, has become almost a Utopian idea, a forlorn hope. Though urged with all the force that truth could impart, and enforced with all the appealing earnestness that the gravity of the subject could inspire, yet your views and wishes have not impressed themselves on the schools to such an extent as to change their course of action. It seems to me that all hope of reform through this means must be abandoned. Nor can we expect to reach the end proposed by measures of State legislation. The obstacles here are too palpable to need enumeration. They are many, and they are unsurmountable. Almost any body of medical men may obtain a charter for a medical college in most of the States of this Union, with pretty much such regulations and privileges as they may agree upon among themselves and ask for.
>
> I despair, therefore, of seeing this Association attain its object through any of the agencies heretofore employed. If, however, this great work *ought* to be done, it *can* be done. I believe it is within the reach of the power of this Association. But I can see no mode by which it can be accomplished, except through FEDERAL LEGISLATION.

Perhaps the most significant statement made at the 1869 convention was that of Samuel D. Gross who had been the delegate to Great Britain. Here comes the first suggestion for a weekly medical journal owned by the Association as a necessary project for the advancement of medicine in our country and the promotion of the work of the Association.

Significant also was the continuing drive toward the prohibition of alcoholic liquors. The *Transactions* contain a report of almost 100 pages on the relations of alcohol to medicine, ending with an apology because the report is not longer. The report was made by a believer in teetotalism and provides such a horrible list of mental disturbances, crimes and other reactions resulting from too much participation in the "demon rum" as to have frightened any one other than the hardy citizens who heard it.

(To be continued)

THE DOCTOR REVIEWS HIS PORTFOLIO

WALTER J. J. SMITH
New York

(NOTE.—The investment mischief that doctors get into with a high degree of regularity seems to stem out of a violation of one or more of the investment fundamentals. The following article briefly reviews these fundamentals. It suggests one method to aid in surmounting these difficulties.—ED.)

Did the bull market end in May-June of 1946 or are the current low prices of securities merely excellent buying opportunities in a bull market that has not yet ended? What investment policy should the doctor adopt? Furthermore, what issue or issues should he buy? There are as many "expert" opinions on both sides of these questions as there are people to voice them, and their number is legion. But, irrespective of which side of this problem history will eventually prove to be right, there are certain things the doctor can do to put his financial house in sounder shape. All of them boil down to a question of examining his portfolio in the light of the degree to which investment fundamentals are being applied and then making the changes according to the findings.

It seems incredible that a man will spend a lifetime studying his profession in order to make a success of it and then, when he has reached his goal, take his life savings and "invest" them in various securities with no more study than he employs when purchasing a hat or a pair of shoes. Yet that seems to be the perennial experience of far too many of the doctors. Undoubtedly there are quite a few who today are looking at some brightly colored stock certificates in their vaults and trying to find out just why they were purchased. Was it for income or for speculation? To say that even a little research went into the issues before their purchase is to be charitable. To say that each and every issue was purchased by the doctor only with a view to its desirability in his entire portfolio and that the portfolio was properly balanced and geared to his specific investment requirements is to say that that doctor is a very unusual one. As a practical matter he is a definite minority, for such a person is the exception and not the rule whether he be doctor, plumber or banker. Is there any wonder then that he comes to financial grief with an alarmingly high degree of regularity?

Look at the problem in this manner. There are three fundamentals that must be observed if a better than average investment result is to be expected. The first one is selection, researched selection. Stated simply, it means that you should pick your securities only after careful study of all pertinent facts concerning each stock and bond, first as to fundamental value and then as to extent to which it meets your major investment objective of income or appreciation. If you are not trained to do it (and the chances are you are not) or you have no time to do it (and the chances are you haven't if you are a successful doctor) then by all means see that a thoroughly experienced security analyst, preferably a specialist in each of the industries involved, does it for you. Specifically, your investment dealer should have the necessary research facilities to do this job.

After you have done this, diversify your risk. There is no perfect investment. No one individual is infallible. No one person knows all the answers. You or your adviser might have forgotten some detail, small enough but important enough, to offset the advantages of the other good factors. New tax laws, products or competition might upset all your calculations. It has happened. Stated another way, don't put all your eggs in one basket, no matter how good the basket appears to be at the moment.

Finally, you should watch the baskets. If you can't do it yourself or don't feel qualified to do it, then by all means see that a competent investment counselor does it for you. As you probably know from your own experience, to "buy something good, put it away and forget about it" has been a highly dangerous and expensive policy to employ. In fact, that idea is just about as silly as the patient who takes a complete physical examination, gets his doctor's O. K. and then concludes he never has to take another trip to his doctor. The records are full of "good" securities that blew up in the investor's face under a policy such as that. Here is the basic reason for that experience. It must be realized that the individual purchases "risks," not securities, and these "risks" must be watched continuously. Some securities represent greater risks than others. For example, U. S. Government bonds have a smaller risk factor than corporate issues, but all are risks varying only in degree with the risk factor increasing down the quality scale from U. S. Governments.

There you have, briefly and simply, the principles of investment success. Violation of any one of these three fundamentals will be enough to give you a special invitation to a choice spot behind the financial "8 ball."

Perhaps you say "That sounds easy. But, if that is all that has to be done in order to have some assurance of a satisfactory investment experience, why do so many doctors come to grief?" Now that is a reasonable question. Fortunately it is not a difficult one to answer. Let us examine those fundamentals again in the light of practical application. To get "expert" suggestions for investment purchases is a simple matter. Investment houses and statistical services are forever compiling such lists and distributing them freely. Consequently the question of selection is less difficult to handle than the other two factors of diversification and supervision. Stated quite succinctly, the real answer to this problem in most cases is "insufficient money." Because of insufficient money it is impossible for the investor to secure the necessary diversification of risk. Simple arithmetic will show the reason. Just to buy 10 shares of each of the common stocks that comprise the Dow Jones Industrial Average would cost the investor (at recent levels) about $23,000 plus commissions. If he wanted to add a few high grade bonds for capital stability another $5,665 would be necessary even if he was to put into the list only one of five different bond issues. No analyst would seriously consider this addition of one bond each as adequate diversification, yet it would represent an additional commitment that an uncomfortably large number of persons could not afford on top of their original investment. If a higher "fixed" return was desired and a somewhat better security balance was required, about $5,175 more would be necessary in order to add about 10 shares each of five different good grade preferred issues in today's market. In other words, a minimum

---

The author has been in the investment field since 1928. He has been security analyst, investment counselor, financial writer and a member of the editorial staff of one of the oldest national and business investment magazines in the country. He is now associated with the National Securities & Research Corporation. He holds a Bachelor's Degree in Economics from New York University, and a Master's Degree in Investments from the Graduate School of Business Administration of New York University.

commitment of some $34,000 plus commissions would be necessary if today's investor wanted to buy a minimum "balanced" investment program. There is one point that should be clearly understood here. These statistics are easily presented, but long association with all kinds of investors prompts the thought that the money to buy the securities is not so easily got. There is no evidence that has come to my attention that would support the belief that the typical investment portfolio is as large as this amount or, more specifically, that the average doctor has much if any more than this "minimum" amount of money invested in the securities markets.

Therefore, aside from representing a sum of money far in excess of an amount the average investor would seem to have available even today in order to secure a minimum amount of diversification and also representing an average size "balanced" portfolio that may be on the liberal side for the doctor, another factor must be considered. This figure would represent a sum of money that competent investment counsel could not afford to place under continuous supervision at the present time except under certain specialized conditions. In other words, even this figure—considerably in excess of the amount that the average person has invested—does not enjoy the benefit of continuous supervision. The alternative to this problem is for the doctor to supervise the portfolio himself, a choice by no means pleasant, in general not feasible and most often not profitable.

Just how valid these conclusions are to a specific investor will of course depend on the particular case. In any given instance the problems of diversification and supervision may be more or less serious, depending on the actual sum of money involved. But, in general, with two of the three investment fundamentals standing excellent chances of being violated because of insufficient money, the average doctor appears to be gambling on Lady Luck to help him solve his investment problems. While she has smiled on many investors from time to time, that lady is notoriously fickle in her affections. Therefore it would not seem to be a very strong base on which to build an investment estate.

SPECIALTY MUTUAL INVESTMENT FUNDS

Is the doctor to conclude from this that he should not be "in the market" if his investable funds amount to only a few thousand dollars and he has neither the time to watch his portfolio nor the knowledge to supervise it even if he had the time? Not necessarily. Several methods have been developed (with varying degrees of success) to get around these difficulties. For example, over the past several years an increasing number of persons have been purchasing the shares of the mutual investment companies in an attempt to get "from under" these problems and thereby improve their chances of arriving at their specific investment goals. Some indication of the extent of the trend toward this end of the investment business might be noted from the fact that, as of a recent date, there were some $1½ billion in assets in these funds and approximately 500,000 shareholders were represented in seventy-three different companies. Sales in 1945 amounted to $292 million and for 1946 were running at a rate of better than $400 million.

The reasons for this recognition are not difficult to see. Portfolios of the "mutual" companies offer the investor a choice ranging from volatile, low priced common stocks to good grade bonds. Whatever the investment need of the individual (income or appreciation) there is a portfolio to fill it. As a matter of fact, choosing a mutual fund to suit one's investment requirements and objectives is as easy as picking an individual stock and, judging by experience of the past several years, a generally more satisfactory procedure. He can choose among investment companies that have different kinds of bond funds as well as companies that have different kinds of preferred stock and common stock funds and finally companies that have so-called balanced funds where the proportion of bonds, preferred stocks and common stocks shifts in accordance with the managements' opinion of the business and economic prospects. It is felt that this method of investing requires no detailed knowledge of individual securities on the part of the professional man and presumes no time in his working schedule to "supervise" them. Yet, at the same time, it sacrifices none of the highly important investment advantages of careful selection of stocks and bonds, proper diversification of issues and continuous supervision of them. On the contrary, it adds the skill of the professional (in the form of the particular fund's investment managers) to the supervision of each individual investment company portfolio and the safety factor of considerably wider diversification to most personal portfolios than would be possible or practicable by employing customary investing methods. *This is purely the mathematical result of cooperative investment action.*

The specialty mutual investment funds (wherein each fund is geared for a specific investment objective such as income or appreciation) represent an interesting modern development in the investment field. They are founded on the simple principle that a group of individuals by pooling their capital can obtain at relatively low cost the same investment advantages that large financial institutions and very wealthy investors enjoy. Additionally and because each fund is geared for a special investment purpose, it permits the doctor's investment estate to be designed and operated in accordance with his specific objectives, whether that objective be income, appreciation or a balance between them, whether his objective be capital conservation (through the use of bond funds) or capital appreciation (through the use of various common stock funds). It is only necessary to purchase the fund or funds that have the kind of securities in them to meet his objective, and this is a matter to be worked out by the doctor and his investment adviser. Because of its flexibility it permits an estate that can be built up or drawn down in part as personal circumstances dictate without in any way affecting the balance of the rest of the program. Quite clearly there are certain personal circumstances wherein bond funds (and only bond funds) are mandatory. On the other hand, there are other doctors so situated that more speculative positions can and should be adopted. Furthermore, there are clearly times in every bull market when logic calls for a major concentration of invested money in bonds and clearly times when the emphasis should be on common stocks. Because mutual investment shares can be liquidated on demand, the doctor can adjust his program in this manner. His investment portfolio (as represented by his holdings of mutual fund shares) can be moved quickly and conveniently from a defensive position (capital conservation using certain types of bond funds in uncertain market conditions) to an aggressive position (capital growth by using certain types of common stock funds in periods of rising stock prices) and back again, in accordance with the major swings of the business cycle. In this manner the investor is able to sidestep entirely the problem of what stock or bond to buy or sell. His only question is one of timing his purchases and sales in the class of securities to meet his objective. In fact, it is possible for all or a substantial percentage of the doctor's investment portfolio to be adjusted in this manner with a minimum of effort and worry on his part.

There are certain "detail" advantages also inherent in the use of these funds. Because of the "pooling" action of his investment through this medium, it affords a simplification of his tax and estate accounting with respect to his security holdings that cannot be surpassed by the average portfolio employing the usual methods of stock and bond buying. Furthermore, it represents an investing medium that is subject to close federal and state regulation. Finally, there is no penalty on the small buyer such as is represented by the "premium" paid on the purchase of an "odd lot" of securities on the large exchanges, nor is there discrimination in management fees between the large and the small investor.

Although the primary objective of the mutual fund management is to do better than most investors do for themselves whether their objective is income or appreciation, there is nothing mysterious about their methods. In order to do this job the investment managers of each fund rely on the rigid employment of the three fundamentals already referred to—selection, diversification and continuous supervision, the same factors the doctor must observe if he hopes to achieve better than average results in his own portfolio operations.

The life insurance industry has a very precise way of describing the result of a purchase of a life insurance policy. "At the stroke of a pen, you have created an estate and hired the people to manage your affairs." This action has its counterpart in the securities field. When he buys the shares of the mutual investment funds suggested by his investment adviser, the doctor creates what is in effect a personal investment account. By this simple action he has hired a bank trustee or custodian who is responsible to him for holding in safekeeping the securities purchased for his account. By the same token and without additional expense, he has hired accountants to keep his books and lawyers to see that his investment affairs are in proper shape. When he bought those shares he thereby employed experienced investment managers to handle his portfolio in exact accordance with his own investment requirements. In other words, he has employed these people to do for him the things he would have to do if he had research facilities and training as well as the time and inclination to do it himself. Finally, it should be remembered that he has hired these people to do this work for him as long as he retains his shares in these funds. He will continue to hold those shares—and thereby hire these people—only as long as the job they do is satisfactory to him.

Clinical Notes, Suggestions and New Instruments

A NEW METHOD FOR FINGER TIP AMPUTATION

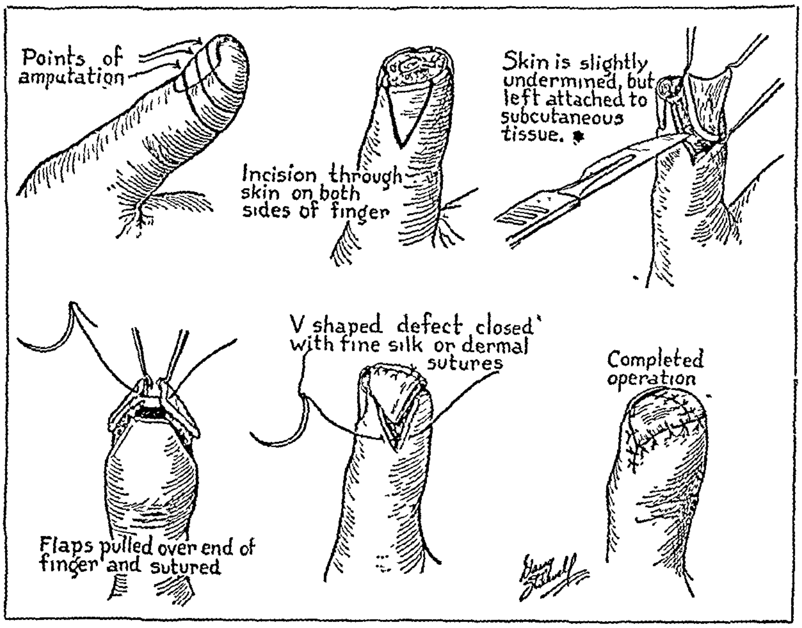
WILLIAM KUTLER, M.D.
Cleveland

A new technic for repair of finger amputation was first published in February 1944. Since that time many additional cases have come to my attention. As a result of this experience, several improvements have been effected.

INDICATIONS

Use of this technic is indicated:

1. For fingers or toes in which the tips are destroyed but the nail matrix is still intact or only slightly injured.
2. In any extremity where further shortening by a ventral flap technic is not desirable (*a*) because the function at that joint may be further decreased or (*b*) because the stump is already short for an appliance.



Points of amputation
Incision through skin on both sides of finger
Skin is slightly undermined, but left attached to subcutaneous tissue. *
Flaps pulled over end of finger and sutured
V shaped defect closed with fine silk or dermal sutures
Completed operation

Steps in new technic for repair of finger amputation. * Since this illustration was first published experience has shown that undermining is not necessary.

The technic which has given the best result is as follows: The end of the crushed finger or thumb is scrubbed thoroughly with soap and water and every particle of foreign matter is removed. All devitalized tissue is excised and the tip of the phalanx smoothed. Two triangular skin flaps are prepared, one on each side of the finger, by making a V-shaped incision on each lateral aspect with the apex pointing proximally and the base distally. It has been found that if the incision outlining the triangular flap is carried down through the subcutaneous tissue the skin flap will became loose enough to be pulled over the tip of the finger. Undermining of the skin flap is not only unnecessary but undesirable, because in some instances the blood supply is impaired and the skin flap sloughed. The flaps are drawn across the end of the finger and sutured together across the midline with fine interrupted silk or dermal sutures. The triangular flaps are further secured by several sutures around the circumference of the finger. Occasionally, it is necessary to place a suture at the dorsal aspect in order to hold the flap right up to the area where the nail will eventually come through. A large dressing is applied which is not disturbed for seven to nine days. Healing usually takes place without infection.

ADVANTAGES OVER THE OLDER METHOD

1. The end result is a smooth, rounded finger tip which is actually slightly lengthened without impairment of its function.

With the ventral flap method, the finger is shortened from ¾ to 1 inch (1.9 to 2.5 cm.), and there is considerable impairment in function.

2. The finger tip is not painful or tender. If the area is allowed to granulate, the result is frequently a deformed and extremely tender finger tip.

3. *The method is simple to carry out.* Although good results can be obtained with full thickness or pedicle grafts, the procedure is difficult and requires considerable time for complete healing; frequently, due to the sloughing of the grafts, the results with this older method are disappointing.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Therapeutic Trials Committee, a standing committee of the Council on Pharmacy and Chemistry, has adopted the following report, and the Council has authorized publication of the report so that it may be widely disseminated to those who have a serious interest in medical research.

Austin Smith, M.D.,
Secretary of the Council.

Walton Van Winkle Jr., M.D.,
Secretary of the Committee.

THE COST OF CLINICAL RESEARCH

The medical profession and the public have come to recognize that the cost of research, particularly medical research, is enormous. The opinion is often expressed that in the case of medical research the principal cost arises from laboratory studies. It does not seem to be generally appreciated that clinical research, if properly performed, is often as expensive as laboratory investigations.

Unfortunately, clinical research has not, in many instances, received the financial support to which it is entitled. This lack of support has resulted in the performance of poorly controlled and ill conceived investigations the data from which do not advance the science of medicine, by reason of incompleteness and unreliability. Admittedly, merely increasing the size of the grants made for clinical investigations will not insure better results. However, adequate financial support will enable the competent investigator to do his best work.

In order to secure more adequate support of clinical research, all participants must develop an appreciation of the factors involved in the cost of such investigations. The group supplying the funds, such as universities, foundations, commercial concerns or private donors, must be prepared to make grants of sufficient size to cover both the direct and the indirect costs of the proposed investigation. The investigator must understand and estimate with some precision the expenses which will be incurred if he is to do an adequate investigation. Both the grantor and the grantee must play fair; neither side should compromise to the detriment of the research problem.

FACTORS TO BE CONSIDERED IN COST

(*a*) *Professional Assistants.*—It is not customary for investigators who derive their personal income from salaries from hospitals, clinics or universities or from private or industrial practice to accept personal remuneration for performing research. Research may be considered a privilege and a duty of those members of the medical profession who are equipped by training and experience, as well as by natural endowments, to conduct original investigations.

Often, however, the investigator must employ one or more assistants, such as residents or young instructors, to carry out the details of the investigation. These assistants may devote all or a substantial part of their time to the investigation. At times they may be employed solely for the purpose of assisting in research, and therefore their salaries are a proper charge against the funds supplied for the investigation. The charge should be based on an actual appraisal of the amount of time they will devote to the investigation. Research funds should not be used to get professional help cheaply for the hospital or clinic.

Evaluation of prophylactic and therapeutic measures has often been seriously retarded by inadequate collection and analysis of quantitative data. Too often sole reliance has been placed on uncontrolled clinical impressions and experience. Consultation with an expert statistician with regard to the planning and conduct of a clinical investigation will often be desirable. Statistical analysis will often be necessary for reliable evaluation of the data collected. Ideally there should be proper training in the medical schools in the handling of quantitative data. As things are at present, funds for statistical consultation will often be necessary.

(*b*) *Technical Assistants.*—Clinical research no longer is confined merely to subjective observations. Objective measurements of the function of various organs and systems, pathologic examination of tissues obtained by biopsy or at operation form an essential part of most clinical investigations. These tests are often time consuming and require skilled personnel especially trained in these technics. Usually universities, hospitals and large clinics have such technical assistants on their staff. Unfortunately, their time is usually devoted entirely to the tests necessary for the routine diagnosis and care of patients. The superimposition of a research project on the ordinary duties of this group often results in curtailment of many tests which might be performed advantageously. In addition, it may seriously affect the adequate performance of the regular duties of the staff. It is often necessary, therefore, to employ additional technical help whose sole duties are in connection with the research problem. The salaries of such personnel are a legitimate charge against the funds supplied for the project.

Many of the observations made on patients are performed by the nursing staff. Hospitals, particularly those receiving charity or part pay patients, are almost universally understaffed with nurses. Furthermore, the turnover in nurses is high because of competitive bidding for their services. An important factor in the successful prosecution of clinical research is a continuity in nursing service. To insure adequate nursing care it may be necessary to pay a premium for such special duty or hire additional nurses outright. The cost of such additional service should be a legitimate charge against the research funds.

(*c*) *Clerical and Stenographic Assistants.*—Proper record keeping is essential to the successful prosecution of any research. Laboratory workers have long recognized the importance of complete records of experiments written at the time the observations are made. Many clinical observers are more lax in the matter of records, often depending on nurses, medical students, assistants or others to record the pertinent observations. These aides have many other duties to perform, and "paperwork" is considered drudgery and is often postponed, resulting in dependence on an imperfect memory. Adequate clerical and stenographic assistance can obviate this difficulty and, in addition, such personnel can prepare the charts, reports and so on that should be made as the investigation progresses. Usually full time clerical or stenographic help is not necessary except where the clinical study is of great magnitude. In budgeting this item, the time to be devoted to this task should be appraised and charges made accordingly.

(*d*) *Expense of Patients.*—Clinical investigations require more than ordinary observation of the patients under study. It is often desirable to hospitalize patients who would otherwise be treated as outpatients. In such instances the patient cannot be asked to bear the cost of hospitalization nor can these funds be legitimately requested from the hospital, school or agency supplying the facilities. The cost must be borne by the research grant.

Patients who would ordinarily be in the hospital for treatment may be asked to remain longer than usually required in order that adequate post-treatment observations may be made. The extra expense entailed in keeping such patients hospitalized beyond the usual time should be paid from the research funds.

(*e*) *Equipment.*—It is rarely necessary to expend funds intended for clinical research for large or expensive equipment. Most institutions have such equipment, but occasionally the nature of the problem will require the use of some instrument or apparatus that is not part of the regular equipment of a hospital or clinic. If this equipment is unexpendable, i. e. not used up or diminished in value during the investigation, the proportion of its cost to be paid from funds for research must be a matter of negotiation. At times the entire purchase price may justifiably be charged to the research fund, particularly if the equipment has no uses other than as a research tool. In such instances, equipment of this nature should not be purchased unless absolutely essential to the investigation. The probable results must justify the expenditure.

If the equipment is expendable and is no longer serviceable after completion of the investigation, the entire cost should be chargeable to the research funds.

(*f*) *Supplies.*—All supplies such as animals, drugs, chemicals, stationery and postage used for the investigation should be computed as part of the expense to be reimbursed from the funds supplied for the investigation.

(*g*) *Project Overhead.*—In addition to the direct costs of an investigation which have been discussed, there are other expenses more difficult to ascertain. Usually these items are overlooked in estimating the overall expenditures for research, but since they are real they must be borne by some one. Usually the burden of meeting such expense has been met by the institution in which the research has been performed. However, rising costs, diminished endowments and other factors are making it more difficult for institutions to meet such costs. Hence an allowance must be made for "project overhead."

Overhead expenses may include the cost of extra janitorial service, unusual use of utilities such as gas, electricity and water, extra laundry for staff and patients, telephone calls and postage. These items cannot be calculated with accuracy, and it has become customary to assign a fixed percentage of the total cost of the project to "overhead" expense. This percentage varies widely with the institution and may range from 10 to 50 per cent. In deciding the figure to be used, thought must be given to the nature of the problem, the time involved in completing the study and the extent to which institutional facilities will be used.

(*h*) *Contingent Fund.*—Since the costs of conducting a research program cannot be estimated with accuracy to the last dollar, and since unforeseen expenses may arise during the investigation, it is usual to provide a contingent fund to cover such emergencies. The amount to be set aside for a contingent fund will vary with the total cost of the project and its nature but is usually not more than 5 or 10 per cent.

(*i*) *Other Expenses.*—Although the items just discussed constitute the principal costs of clinical research, there are one or two items of expense which may arise in certain problems. Occasionally it may be necessary to travel to meetings or conferences. Such travel expenses should be included in the budget as a separate item. Some projects may require extensive social service follow-ups. This is particularly true in problems involving epidemiology, venereal diseases or occuptional diseases. The cost of such follow-up and the salaries, in whole or in part, of the social service workers should be chargeable to the research funds.

ESTIMATING THE COSTS OF CLINICAL RESEARCH

Before a reasonably accurate estimate of the cost of any research project can be made, it is necessary to prepare a fairly detailed outline of the plan of investigation. An effort should be made in preparing this plan to foresee all possible contingencies. A careful appraisal of the amount of laboratory work which will be necessary, the number of patients who will be studied, the amount and type of assistance which will be needed, and the amount of time necessary to complete the problem should be made.

From a detailed plan of investigation it will be possible to arrive at a fairly accurate estimate of the cost of the project. Each item discussed should be considered and the amount required to defray the expense should be entered in the budget. The detailed budget should be presented to the sponsor of the project in justification of the sum requested.

In general, past experience will serve as a useful guide in estimating costs. Such items as salaries and cost of equipment can be calculated with precision. The expense of patients and the cost of supplies will be subject to some error, but if the project is carefully planned this error can be held to a minimum. The overhead and contingent fund cannot be calculated accurately but must be based on sound reasoning.

DISBURSING RESEARCH FUNDS

In many institutions it is a common practice to deposit research grants in a special fund and draw against this fund as the need arises. Bookkeeping details are usually handled by the business office. Unfortunately, it is not often possible to review the records of disbursements and gain an accurate statement of the amounts spent for the various items discussed. Because it is good business and because it will be useful in estimating costs of future research, it is desirable to indicate for what purpose each disbursement is made.

FUTURE TRENDS IN RESEARCH COSTS

Clinical research can no longer be supported on a shoestring if it is to contribute to the advancement of medicine. The day when useful information could be obtained by the grant of a bottle of pills and a few hundred dollars is past. The advances made in the methods of clinical research and the complexity of the problems have increased the costs enormously. Universities and privately endowed institutions can no longer contribute the major portion of the funds for clinical research. These funds must be derived from private sources such as foundations, private donors, industry or public funds. Much is already being done in this direction, but there are still many donors of research grants who do not appreciate the factors involved in the cost of research, and there are many investigators who have not taken the time to analyze their expenditures.

Investigators are not generally interested in "short term" studies. Such investigations usually do not contribute to medical progress in proportion to their cost. Furthermore, it is usually impossible to provide adequate professional and technical assistance for short term investigations. Occasionally a small study may be incorporated into a major research project without disrupting the project or increasing the cost prohibitively. However, this must be regarded as a compromise, since the primary interest of the investigator lies with his major study, and he accepts the short term study only to secure additional funds to assist his program.

Long range studies, though costly, usually give greater returns to both the investigator and the sponsor for the amount of money expended. Furthermore, such long range projects often open new fields of investigation, lead to the development of new therapeutic agents and provide training for young investigators. Therefore, sponsors of research projects should undertake the support of long range fundamental projects even though the total number of projects which may be supported is reduced.

It is becoming apparent that much expense and time can be saved if certain appropriate clinical investigations proceeding in various centers can be coordinated through some impartial central agency which will provide a means for rapid interchange of information and which can assist in integrating the work of various investigators. Such coordination was performed by the Office of Scientific Research and Development and the Committee on Medical Research during the recent war and resulted in great advances in medicine. Owing to necessity of the emergency, the coordinating agency often had to impose its will on the investigator; but the freedom of the investigator must be preserved in peacetime. Any coordinating agency should be just that and should not attempt to dictate how an investigation is to be performed or how much money is to be spent on it. It is moreover neither desirable not within the capacity of any such voluntary coordinating agency as the Therapeutic Trials Committee to function with respect to more than a small fraction of the total number of clinical investigations in progress at any time.

The Council on Pharmacy and Chemistry has established the Therapeutic Trials Committee for the purpose of assisting sponsors wishing to support research and investigators anxious to participate in worth while therapeutic research. It is hoped that this committee will enable medical progress in therapeutics to be made in appropriate instances with less waste of both time and effort than is possible without some central coordinating agency. The overhead involved in the committee operations is borne by the Committee, thus allowing all funds derived from sponsors to be used for actual research.

SATURDAY, JANUARY 4, 1947

THE CENTENNIAL YEAR

1947 is Centennial Year for the American Medical Association. The history of the Association is now being published serially in The Journal. Physicians interested in organizational work will find in the history of the Association many situations which recur in successive generations. The instructional value of careful study of the processes by which the Association came into being, its motivations, its problems, its technics and its progress cannot be overestimated.

As was reported to the House of Delegates at its midwinter session in Chicago in December, plans are already well under way for celebration of the Centennial at the Annual Session in Atlantic City June 9 to 13. The program which was outlined in skeleton form is fast assuming completion.

On June 7 the Board of Trustees and officers of the Association will tender a banquet to leaders in the industries and occupations associated with medicine, at which distinguished speakers will comment on the influence of American medicine on the nation's progress.

On Sunday, June 8, a religious service will be held in the great hall in Atlantic City at which three great religious leaders will speak on the spiritual aspects of medicine and health Those scheduled at this time include Monsignor Fulton J. Shean of Catholic University, Washington, D. C., Rabbi Joshua Liebman of Boston and Dr. Ralph Cooper Hutchison, president of Lafayette College. On this Sunday ministers throughout the nation will be asked to devote their sermons to a similar topic. It is hoped that in all the communities throughout the country physicians who are associated with religious groups will take up with their spiritual leaders at an early date the desirability of such a program. It is hoped furthermore that arrangements can be made, as now seems likely, for a national broadcast of the religious services from Atlantic City.

The House of Delegates of the American Medical Association will begin its Centennial Session on Monday, June 9, in the Traymore Hotel. Simultaneously the largest technical and scientific exhibit ever developed by the American Medical Association will open in the great Convention Hall. At the same time an exhibit for the public depicting the progress of scientific medicine will be made available in one of the large spaces on the boardwalk.

The General Scientific Meetings will include reviews of scientific advancement in most medical fields. The tentative program was published in The Journal of Dec. 28, 1946, page 1091. The present status of our knowledge of such subjects as the antihistamine drugs, poliomyelitis, cancer, the antibiotic drugs and radioactive products in medicine will be presented by distinguished leaders of research in these fields. There will be panel discussions on the modern management of heart disease, emergency surgery and antibiotic therapy. Distinguished guests from abroad are scheduled for each of the programs.

A motion picture program is being developed especially for the occasion and will include among other special showings a film on the evolution of the scientific medical motion picture.

The section meetings planned for the Atlantic City Session will be held as usual. On the program for each section there will be a foreign guest who is a leader in his specialty. Another speaker will present a historical paper on the development of the specialty concerned during the last hundred years. Subsequently these historical contributions will be assembled in book form.

The eminent foreign guests of the Association will be presented at the opening of the General Session, at which time the President makes his address.

Many other events are in process of development. The committee on the Centennial Celebration is confident that the program for this occasion will represent a high point in the assemblages of physicians anywhere in the world. In order that arrangements may be made to house and feed properly the great number of visitors who will attend, all who contemplate coming to the Atlantic City Session should communicate at the earliest possible moment with the Subcommittee on Hotels, Dr. Robert A. Bradley, Chairman, 16 Central Pier, Atlantic City, N. J.

"ANTIDOTAL" PROPERTY OF FILTRATES OF PENICILLIUM NOTATUM

Fleming, Florey, Chain and other early investigators were concerned principally with the bacteriostatic and bactericidal properties of the cultures of Penicillium notatum. The effect of these cultures on bacterial toxins was not investigated. Neter[1] in 1945 found that clavacin and pyocyanase decreased the toxicity of tetanus toxin, whereas penicillin, streptomycin and actinomycin A failed to do so. Sodium penicillin in amounts of 500 to 5,000 Oxford units failed to decrease the toxicity of tetanus toxin or caused only a minimal reduction in toxicity. Ramon and Richou[2] showed that filtrates of Bacillus subtilis are capable of profoundly affecting or even completely destroying diphtherial, staphylococcic and tetanus toxins. Richou and the Ramons[3] also demonstrated that filtrates of cultures of Penicillium notatum possess the same "antidotal" power as B. subtilis against certain exotoxic bacterial toxins. When 2 cc. of staphylococcic toxin of the strength of 400 hemolytic doses to 1 cc. were mixed with 2 cc. of a filtrate of a culture of Penicillium notatum containing 90 international units of penicillin per cubic centimeter and the mixture was kept in an incubator at 37 C., the 800 hemolytic doses of the toxin contained in this mixture were completely inactivated in three hours, while 1,600 doses were neutralized in six hours. Experiments on guinea pigs showed a complete destruction of 150 fatal doses of diphtheritic toxin when mixed with 2 cc. of a filtrate of Penicillium and kept for twenty-four hours at a temperature of 37 C. The toxin itself when exposed to the temperature of 37 C. for the same duration of time did not lose any of its toxicity. The toxin-filtrate mixture did not lose any of its effectiveness when exposed to temperatures of 18 or 20 C.; when exposed to a temperature of 5 C. the mixture produced its effect at a slower tempo. Heating of the filtrate to 55 C. for one half to one hour did not increase its "antidotal" property. The filtrate becomes less effective at temperatures above 60 C. Addition of 0.5 cc. of solution of formaldehyde to 100 cc. of the filtrate with or without heating it to 55 C. for one half to one hour did not appreciably alter its effectiveness. The inactivating or "antidotal" property of the formaldehyde treated and warmed filtrates of Penicillium notatum persists for as long as three months if kept at a temperature of 5 C. Addition of human serum to the mixture of staphylococcic toxin and filtrate of Penicillium notatum does not alter the "antidotal" effect.

The authors object to the use of the term "antitoxic" because the latter applies to the property of antitoxins to neutralize the corresponding toxins. The term "antidotal" seems to be justified in the present case because it describes a substance capable of annulling the noxious effect of bacterial toxins whether that is accomplished by decomposing them or by combining with them. Penicillin apparently loses this "antidotal" property in the process of its derivation and purification. The authors believe that certain precautions observed in the process of preparation of penicillin may at least partly avoid these undesirable effects. They stress the importance of developing technics for concentration and purification of penicillin which will conserve these antagonistic principles. An excellent precaution is to add formaldehyde in proper proportion to the cultures of Penicillium before their filtration or to the filtrates themselves or to both or to subject them to the action of formaldehyde and heat simultaneously. In this way the filtrates will be protected in the course of their preparation and in the course of their utilization against contamination with certain micro-organisms which favor the producton of penicillinase, the latter being destructive of the antagonistic properties of penicillin.

The discovery of the "antidotal" quality possessed by the crude filtrates of Penicillium notatum suggests that the same property is probably possessed by filtrates of other antagonistic germs and enlarges greatly the possibilities in the domain of antimicrobic therapy.

SICKLE CELL ANEMIA, A RACE SPECIFIC DISEASE

The most significant feature of sickle cell anemia is not its characteristic bizarre deformation of erythrocytes but the fact that it is apparently the only known disease that is completely confined to a single race. Other diseases may be limited to a specific group of people because of disease provoking customs and habits (e. g. betel nut cancer) or to a given geographic area that may or may not be inhabited by a homogeneous group (e. g. trypanosomiasis). But foreigners practicing the local customs or residing in these areas become equally liable to the diseases. Sickle cell anemia, however, is independent of either geography or customs and habits. Its occurrence depends entirely on the presence of Negro blood, even though in extremely small amounts. The disease was discovered in Chicago in a Negro medical student whose forebears had long since adopted Western civilization. Hundreds of cases of sickle cell anemia had been demonstrated in American Negroes before it was even found to occur in Africa, the accepted place of its origin.

The publication by Herrick[1] of the original description of sickle cell anemia was followed by numerous reports of similar cases confirming it as an entity. All the cases were at first in Negroes. Then further reports began to appear indicating its occurrence in the million mark and three approach 500,000. We shall soon have 5,000,000 people enrolled in our voluntary prepayment plans.

---

[1] Herrick, James B.: Peculiar Elongated and Sickle Shaped Red Blood Corpuscles in a Case of Severe Anemia, Arch. Int. Med. *6:* 517 (Nov.) 1910.

Such facts are encouraging, but your reference committee is mindful that to get thus far small groups of physicians in various states have worked hard and with great sacrifice these many years to accomplish this tremendous task in behalf of social betterment. Only those who have worked on the early medical care plans can know the soul-tiring difficulties and obstructions that appear in the uncharted course of these new ventures. Even today no group but the medical profession has cared to pioneer very far away from the well known limits of surgical and obstetric care insurance. In these two fields, as well as in hospitalization insurance, actuarial statistics are now available to permit the expectation of a sound fiscal experience. But to add to this coverage the choice of comprehensive or even limited medical care under a popular policy premium—that is another matter. In essaying to do this the physician supporters of plans in various parts of the country have surrendered on the unit ratio basis literally hundreds of thousands of dollars for services rendered so that the public might receive the 100 per cent full measure of its contract. It appears that in no instance in this country have patients suffered poor medical service or financial loss because of participation in a physician nonprofit voluntary prepayment plan. All honor to the founder pioneers and the loyal physicians contributing to this first chapter of voluntary medical care insurance. But to grow and succeed requires, after all, a foundation of sound economy. The committee counsels the profession at large, this House of Delegates, state and county medical societies and medical care plans, new and old, to keep closely in touch with the Council on Medical Service of the American Medical Association so that they may learn from the authority of experience how to form a sound voluntary care plan, service it properly, make it appeal alike to patient and to physician and how to adapt it to the needs of the community. We now know enough to take the next decisive step forward. Let us do it for the sake of the American family.

The Council report calls attention to the handling of the technical problems of plan administration by Associated Medical Care Plans. Your reference committee bespeaks a cooperative relationship between these two bodies working on a common problem.

2. National Health Congress: Your reference committee has studied the import of the setting up of a National Health Congress. Further data and statistics are being collected. However, in a supplemental report the Council states its belief that to set up a national health congress as a permanent body is not advisable. It is of the opinion that conferences called for special purposes at certain times are more desirable. The Council, therefore, requests the House to rescind its previous instructions to the Council to proceed with the establishment of a National Health Congress. Your reference committee concurs with this request and recommends that the House take this action.

3. Speakers' Bureau: Your reference committee importunes all state medical societies to establish speakers' bureaus and to cooperate closely with the activities of the Council in this regard. It notes with satisfaction the distribution of material bearing important subject matter to the delegates at this meeting.

4. United Mine Workers Health Fund: Your reference committee notes with satisfaction that the Council on Medical Service is following closely the developments in the bituminous coal situation and the United Mine Workers Health Fund and Welfare and Retirement Fund. The report of the Council at this time is necessarily factual, and any policy relative to these projects must await the release of the survey report now being made by the United States Navy under the direction of Admiral Joel T. Boone.

Your committee recognizes in these proposals a new type of economic philosophy, one with far reaching implications and concerns, which well may influence and possibly change the whole basic pattern of medical practice. The manner in which these funds ultimately will be administered and the instrumentalities through which medical care will be delivered will require our careful study and guidance. Such plans as these doubtless will occupy a prominent place in any collective bargaining of the future by labor and other organized groups. We shall have to project ourselves into this developing situation and play a leading role in the evolution of these plans for medical care.

It would take this occasion to commend the painstaking and patient work of Dr. Walter B. Martin, whose efforts and counsel have already laid the groundwork for wise negotiation and for the amicable solution of the complex problems that will arise.

5. Taft-Smith-Ball Bill: The Council is collecting opinions and suggestions from state medical societies on legislation of this nature. Your reference committee believes it is a province of medicine to take an active, guiding part in health legislation. It envisions the more beneficial results obtained in dealing with health problems when statesmen consult with the members of the medical profession before attempting health legislation.

6. *Hill-Burton Bill*: Your reference committee studied with much interest and with approval a special report of the Council suggesting principles to govern cooperation in the Hill-Burton Bill program. It recommends certain minor changes in the text of the Council's special report as follows:

Eliminate words "and technical personnel" in paragraph in Definition of a Health Center so that the paragraph will then read:

> Definition of a Health Center. From the point of view of the medical profession, a health center is an institution in a community which houses *the public health functions* of a community and which makes available to the medical profession equipment to aid in the prevention, diagnosis, and treatment of disease.

Your reference committee also recommends a change in the paragraph referring to "Radiologic, Pathologic and Other Laboratory Services" to read "Radiologic, Pathologic and Other Medical Services"; a change from the word "special" to "specialist" and a change by eliminating the words "and laboratory" so that that phrase will read, "*to establish radiologic and* pathologic services."

Your reference committee approves the general and specific recommendations of the Council report as follows:

Definition of a Health Center: In view of the importance of this subject, the Board of Trustees has authorized an immediate survey and inspection of existing health centers with a view to determine the nature of the services they render and the necessity for such services in relation to other existing facilities in the communities concerned. Your committee therefore recommends that following the completion of this survey the House of Delegates requests the Board of Trustees, the Council on Medical Service and the Council on Medical Education and Hospitals to prepare a suitable definition of a health center or of health centers of varying types in order to aid the Division of Hospital Facilities of the U. S. Public Health Service in drawing up the regulations for making effective the provisions of the Hill-Burton Act.

7. Public Assistance Programs: Your reference committee commends the Council's interest in ways and means of organizing medical care programs for recipients of public assistance funds. The Council is gathering information and data on such programs. Special attention is being given to the possibility of utilizing existing prepayment plans.

8. Regional Conferences: Your reference committee approves the program of regional conferences.

9. Studies and Publications: Your committee notes that the Council is collecting data and information relative to the medical cooperative movement throughout the country. It is bringing up to date its material on Contract and Group Practice.

Your reference committee agrees to the popularity of the News Letters and hopes for an increasing distribution of this valuable material.

10. Film on Prepayment: The Council in a supplemental report states it has deferred the making of a movie film on

prepayment plans as impractical and too expensive at the present time.

11. Contacts: Your reference committee seeks to encourage the contacts of the Council with many special groups and adds for special consideration hospital groups and the nursing and the pharmaceutic professions. It notes the reports of conferences with private insurance associations. Among problems discussed were simplification of insurance forms and disability claim blanks. Your reference committee urges the House of Delegates to approve the continuation of these conferences.

12. Washington Office: Your reference committee gave especial attention to the report on the Washington office. It now has new quarters, larger and more attractive, at 1302 18th Street, N. W. Reconstruction of the filing system gives an added improvement. Your committee congratulates the Council on its constructive policy toward the Washington office.

13. Headquarters Office: Your committee notes with great satisfaction the enlargement of the Headquarters office. Recent addition of suitable personnel to implement our greater activities is highly commendable.

REPORT OF COMMITTEE ON RURAL MEDICAL SERVICE

The report describes proposals for meetings with organized farm groups and outlines a discussion of the following subjects: (1) bringing and holding well qualified physicians in rural communities; (2) hospitals, facilities and health centers; (3) voluntary prepayment plans; (4) nursing needs of rural communities; (5) health councils as agencies for promoting rural health, and (6) medical care for lower income groups.

Your reference committee approves the exploration of such all important topics. The report points out that in the Hill-Burton Bill priority is given to rural areas in greatest need, but since these communities usually have the least economic resources they cannot meet the two-thirds cost assessed to them in these projects. Each state will need to develop plans and to take action to meet this situation. Your committee is impressed with this farsighted and logical observation. It wishes to emphasize the following paragraph of the report:

> Farmers interested in improving their community want principally a doctor. It is doubtful if much enthusiasm could be stimulated in a public health facility if it did not also do something to bring and hold a doctor.

Your committee concurs in the importance of prepaid medical care and hospitalization plans.

The report speaks of the development of cooperative associations and other consumer-controlled groups for provision of medical care. There are some eighty-nine cooperatives in thirty-one states now operating. Since these groups expect to employ physicians, the report requests that some minimum standard or basic principles involved in such contracts be adopted by this House of Delegates.

Your reference committee recommends the following resolution:

> Although there is some difference of opinion regarding the establishing of consumer cooperative medical care programs nevertheless they are functioning in certain areas of this country; and
>
> WHEREAS, it is necessary that in order to ensure good medical care certain basic principles be formulated; therefore be it
>
> *Resolved*, That this House of Delegates request the Board of Trustees to set up proper standards to be used by cooperative or consumer-controlled groups when providing medical services.

Respectfully submitted,

HERBERT H. BAUCKUS, Chairman.
JOSEPH H. HOWARD.
GEORGE P. JOHNSTON.
J. STANLEY KENNEY.
L. HOWARD SCHRIVER.

On motions of Dr. Bauckus, duly seconded and carried after discussion, the report of the reference committee was adopted section by section and as a whole.

Report of Reference Committee on Reports of Officers

Dr. John W. Cline, Chairman, presented the following report, which was adopted on motion of Dr. Cline, seconded by Dr. Clark Bailey, Kentucky, and carried.

The Reference Committee on Reports of Officers had referred to it three items for consideration. These were: the address of the Speaker of the House; the address of the President of the American Medical Association, and the address of the President-Elect of the American Medical Association.

Speaker's Address.—The committee desires to express its appreciation of the efforts of the Speaker to expedite the business of the House by means of the various changes he has instituted in the past year. It wishes also to commend him on his conduct of meetings of the House.

The committee would like to call the attention of the House to the recommendation of the Speaker that the individual delegates pay close attention to the proceedings of the House; make known their wishes relative to business of the House referred to reference committees, and actively participate in the deliberations of the House.

President's Address.—The committee desires to compliment the President on his brief and appropriate remarks which the entire House heard but of which the committee has no copy to which to refer.

Your committee shares the satisfaction of the President on the past accomplishments of the American Medical Association and agrees with his predictions concerning the future growth, development and strength of the American Medical Association.

The committee, however, would like to call to the attention of the House that the American Medical Association would not be justified in assuming that the present political trend will indefinitely continue and that during the period of peace and freedom allotted to us every effort should be made to strengthen the position of American medicine to the end that should we again be faced with tests similar to those of the recent past, we would find our position much stronger than at present.

President-Elect's Address.—The committee likewise wishes to commend the President-Elect for his remarks of confidence in the future of the Association and agrees that there should be no change in the fundamental principles underlying the scientific program of the organization.

The committee feels that it would impose an added burden on the officers of the Association to require that they render semiannual reports to the House of Delegates. The committee believes that under normal circumstances annual reports are sufficient. It therefore recommends that routine reports of the officers at the ad interim sessions of the House of Delegates be discontinued.

Respectfully submitted,

JOHN W. CLINE, Chairman.
A. R. MCCOMAS.
JAMES Q. GRAVES.
IVAN FAWCETT.
RAYMOND L. ZECH.

Report of Committee to Consider Revision of the Constitution and By-Laws

Dr. F. F. Borzell, chairman, stated that at a meeting during the morning the committee decided that in view of the fact that there is no real emergency as far as any changes in the By-Laws are concerned, and rather than attempt to put forth an incomplete and, perhaps, unsatisfactory revision at this time it would like very much to continue its activity and postpone final action on these By-Laws until June.

In the meantime, however, the Committee would like very much to have expressions of suggestions for changes, or for deletions in the mimeographed report from this House, either this morning or in the interval between now and the first of February or both. The committee hopes that by adopting this procedure it will be able to place in the hands of all the delegates who will be at the annual session a complete and completely edited copy of proposed changes in the Constitution as well as in the By-Laws, so that you may come to the annual session completely prepared to speed the approval and acceptance of the revised By-Laws.

Dr. Borzell suggested that the House go into a Committee of the Whole purely to receive suggestions and opinions without debate of any special details but with the purpose of the committee's securing the opinion of the House so that it can be prepared to make changes; the motion was seconded by Dr. L. G. Christian, Michigan, and carried.

Dr. James C. Sargent, Wisconsin, moved that the House resolve itself into a Committee of the Whole, and the motion was seconded by Dr. George W. Kosmak, New York, and carried.

The House recessed at 10 o'clock to go into session as a Committee of the Whole for the purpose of conveying to the Committee to Consider Revision of the Constitution and By-Laws suggestions from members of the House.

The House at 10:35 a. m. reconvened in regular session with the Speaker, Dr. R. W. Fouts, presiding.

Report of Committee of the Whole

Dr. James C. Sargent, chairman, reported that the Committee of the Whole had been in session and its report consisted largely of informal recommendations to the Chairman of the Committee to Consider Revision of the Constitution and By-Laws, and moved adoption of the report.

Dr. Walter E. Vest, West Virginia, seconded the motion, which was carried.

On motion of Dr. Allen H. Bunce, Georgia, seconded by Dr. Walter E. Vest, West Virginia, and carried, the House expressed its thanks to the members of the committee consisting of Dr. Francis F. Borzell, Chairman, and Dr. Louis A. Buie, Dr. E. S. Hamilton, Dr. Joseph D. McCarthy, Dr. Stanley Osborn, Dr. B. E. Pickett, Dr. Floyd Winslow and Mr. T. V. McDavitt for their work on the revision of the By-Laws.

Amendment to Present By-Laws, Chapter IV, Section 1

The Speaker ruled that since proposed amendments to the By-Laws had been proposed on Tuesday, an amendment should be acted on today.

Dr. Albert F. R. Andresen, New York, moved that there be deleted from section 1 on Nominations, under chapter IV of the By-Laws now in effect, the last sentence reading "No member of the House of Delegates nor general officer of the Association shall be eligible for election to the office of President-Elect or Vice President," and the motion was seconded by Dr. George W. Kosmak, New York, and carried by more than a two-thirds vote, that section 1, chapter IV of the By-Laws at present in effect will now read:

SECTION 1. NOMINATIONS—Nominations for office shall be made orally, but a nominating speech must not exceed two minutes. The Treasurer shall be nominated by the Board of Trustees.

Question of Publication of Rich Report

The question was raised as to how long the Rich Report was to be considered confidential. The discussion brought out that that report is copyrighted by the American Medical Association and may not be quoted without permission from the American Medical Association but that those portions of the report of the Special Committee on Executive Session for Consideration of the Rich Report that were adopted by the House would be printed and would include the portions of the Rich Report to which they referred; advance pages of the report of the special committee would be sent to the editors of the journals of the constituent state medical associations.

Report of Reference Committee on Medical Service

Dr. Herbert H. Bauckus, Chairman, presented the following report, which was adopted on motion of Dr. Bauckus, seconded by several and carried:

The American Cancer Society has established regulations for the control of information services, detection centers, service programs and diagnostic and treatment clinics. The American Cancer Society's control over any of these is exercised only in the distribution of funds with the exception of the information services. None of these agencies can be set up or operated without the approval of the local county medical societies.

This county medical society control pertains not only to permission to set them up but to everything pertaining to their operation, staffing and economic control. The American Cancer Society itself will not own or operate any agency. The only other agency which will have a part in any of them is the American College of Surgeons, which will be requested to inspect the detection centers from a purely professional point of view to determine whether or not they are doing a satisfactory professional job. This will be done just as the American College of Surgeons now inspects diagnostic clinics and hospitals.

The regulations which have been drawn up have been approved by the Professional Advisory Committee of the American Cancer Society, on which there are representatives of the American Medical Association, and by the Council on Medical Service of the American Medical Association.

It is recommended that the House of Delegates give approval to this program.

The program which has been presented by the American Cancer Society for inclusion in its service manual indicates that funds for all elements of its program are given only to agencies which operate to the satisfaction of the county medical society. With the exception of the information service, the part played by the American Cancer Society is merely that of dispensing funds and furnishing volunteers to assist agencies which receive its help, again under plans approved by the county association. Confusion has occurred in the minds of many physicians due to the fact that the United States Public Health Service is also dispensing funds in various states for the control of cancer. This is an entirely separate program from that of the American Cancer Society.

The information service which is operated by the local branches of the American Cancer Society does not diagnose or treat but dispenses information about cancer and assists the inquiring person in meeting his needs for diagnosis and treatment. This service will not be operated except with the continuing approval of the county medical association.

The contemplated inspection of quality of service which the American College of Surgeons is to be requested to undertake is similar to inspections of cancer clinics and hospitals which have been conducted by that organization for many years.

The American Cancer Society is one of the great voluntary health agencies mentioned in the Ten Point Program of the American Medical Association and your reference committee feels that its program should receive the support of the House of Delegates.

Respectfully submitted,

HERBERT H. BAUCKUS, Chairman.
JOSEPH H. HOWARD.
GEORGE P. JOHNSTON.
J. STANLEY KENNEY.
L. HOWARD SCHRIVER.

The House recessed at 11:05 a. m. and reconvened at 11:25 a. m.

Report of Reference Committee on Legislation and Public Relations

Dr. Charles H. Phifer, Chairman, presented a report of the Reference Committee on Legislation and Public Relations, which, on motion of Dr. Phifer, duly seconded and carried after discussion and amendment, was adopted section by section and as a whole. The amended report reads:

1. Resolution on Woman's Auxiliary: Your reference committee has considered this resolution. It is most appreciative of the excellent liaison and educational program that the Woman's Auxiliary has contributed to medicine. Your committee concurs in this resolution and recommends that it be approved by the House of Delegates and that the Board of

Trustees be requested to outline and assist the Woman's Auxiliary in the guidance of its program.

2. Resolution on Appointment of Surgeons General: Regarding the resolution presented with the report of the Committee on National Emergency Medical Service concerning the Surgeons General of the Army, Navy and Public Health Service and the Chief Medical Officer of the Veterans Administration your reference committee suggests substituting the following resolutions:

Resolved, That the Secretary of the American Medical Association inform the President of the United States, the Secretary of War, the Secretary of the Navy and the Federal Security Administrator of the willingness of the American Medical Association, through a committee appointed for that purpose, to confer and cooperate with them in the important question of the selection of a Surgeon General for the Army, the Navy and the Public Health Service; and be it further

Resolved, That the President of the United States, the Secretary of War, the Secretary of the Navy, and the Federal Security Administrator be informed of the intensive study of war medicine which the Association is conducting and that the results of this study will be made available to them.

3. Resolution on Fellowship of Members of Permanent Corps of Veterans Administration: Your reference committee has considered this resolution and recognizes that it falls into two natural divisions: (*a*) The provision for representation of the Medical Department of the Veterans Administration in this House; (*b*) The admission to Fellowship of the members of the permanent corps of the Administration without the payment of dues. Your committee considered these separately.

In reference to the first division (*a*) regarding the representation in the House of Delegates, your reference committee has very carefully considered this question and its responsibilities. It is deeply conscious of the fact that the recent acts of Congress have established the Veterans Administration as a permanent medical corps of the United States, with General Hawley in charge of the program for medical care of the veterans, a position comparable to that of the Surgeon General of the Army, Navy and Public Health Service. Therefore your committee recommends that the Veterans Administration be given representation in the House of Delegates and that the House proceed to take such steps as are necessary to accomplish this.

Regarding the second division (*b*) as to Fellowship, your reference committee believes that due to the fact that the Veterans Administration has been authorized to care for 15 million veterans, the members of the permanent medical corps should receive the same consideration as that given to medical officers of the Army, Navy and Public Health Service with the provision that Fellowship will continue only as long as they remain members of the permanent corps of the Veterans Administration. Such Fellows shall not receive The Journal or other publications of the American Medical Association except by their personal subscription.

Respectfully submitted,

Charles H. Phifer, Chairman.
Thomas P. Murdock.
John J. Masterson.
Lowell S. Goin.
Edward Jelks.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Clarence G. Bandler, Chairman, presented the following report, which was adopted section by section and as a whole on motion of Dr. Bandler, duly seconded and carried:

REPORT OF SECRETARY

Your reference committee has reviewed the Secretary's interim report and duly appreciates the lack of adequate personnel and the shortage of supplies which are essential to the maintenance of the vast volume of work which that officer has accomplished. Your committee approves the report and wholeheartedly endorses the campaign for increased Fellowships. It notes that 3,986 Fellows have been added in the past eleven months and would suggest that the distinction between a member and a Fellow be explained at every opportunity, so that the advantages accruing to Fellows will be better understood.

The additional items in the Secretary's brief report will be more elaborately presented in his report at the next annual Session.

REPORT OF THE BOARD OF TRUSTEES

Your reference committee has perused with considerable interest the reports of the activities of all the councils, bureaus and committees under the direction of the Board of Trustees. Your committee wholeheartedly approves all of these reports. Because of the vast number of individual communications, your committee will refer only to those of especial interest to the House of Delegates.

1. (*a*) The Journal of The American Medical Association and Special Journals: Your committee is fully aware of the difficulties under which The Journal is published and especially would commend the general improvement of all the articles appearing in the various publications of the Association and the business-like manner in which these periodicals are handled. It hopefully looks forward to the elaboration of *Hygeia* and knows that a wider distribution will soon be forthcoming when the obstacles in the shortage of paper have been overcome.

1. (*b*) Directory Department: Your committee has full realization of the many causes for delay in the issuance of a new directory. It trusts that these obstacles will soon be overcome and that a new directory will be published at an early time.

1. (*c*) Report on History of the American Medical Association: It is surely pleasing to know that a compilation of the history of the American Medical Association is in the process of preparation and will be presented in extenso before the Centennial Session in June, 1947. The portions of this material already appearing in The Journal are exceedingly interesting and have aroused a large measure of favorable comment.

2. (*a*) Council on Pharmacy and Chemistry: Your committee realizes that the Council's standard for purity of preparation of all medicaments and the proper labeling of all preparations assures complete protection to the public to whom these materials are purveyed.

The publications of the many activities of this council not only serve to inform physicians more completely but also have definite educational value.

2. (*b*) Chemical Laboratory: The cooperation of the Chemical Laboratory not only serves as a check on the constituents of products investigated by the Council but also assures the approval of only those that are of distinct value to both the patient and the physician.

2. (*c*) Council on Physical Medicine: Your reference committee notes with considerable interest the activities of this council in evaluating useful devices in the field of physical medicine, and especially in separating in its recommendations those that are beneficial from the many that are definitely detrimental to the patients. It also unqualifiedly approves the utilization of the various consultants in the many fields of this council's activities. It can do no better than to quote from a portion of the report which states that: "The successful employment of physical medicine during World War II has had a great influence on the acceptance of physical medicine by the general practitioner." One of the results will be the wide application by the physician of physical medicine in his curative efforts.

2. (*d*) Council on Foods and Nutrition: Your reference committee is of the opinion that this council is doing a most important work and, because of increased responsibility, this council merits not only the continued interest but also the full support of the Association in its efforts. Your committee approves the recommendation for enlargement of the staff to meet the greater demand on its facilities due to postwar expansion.

2. (*c*) Council on Industrial Health: Your committee has a deep sense of appreciation of the multiplicity of the activities of this council. The detailed report is in the hands of another reference committee. However, your committee recognizes the need for cooperation with other agencies and endorses the Council's stand in the Hearing on Public Law 658 enacted by the 79th Congress, wherein the Council insisted on proper safeguards that are essential for the public good.

This Council has brought to the attention of surveying groups the lack of industrial health services in coal mining areas. Your committee recognizes the fact that health and welfare are likely to be important factors in future wage agreements and would add its voice in urging the Council on Industrial Health not only to observe all developments in this field but also to report thereon promptly.

3. (*a*) Bureau of Health Education: Dissemination of proper information in regard to health and needed legislation is essential for the education of the public. It promotes an understanding of what medicine represents in securing better health for our people. Your committee notes with pleasure the employment of the several methods for conveying information, such as radio broadcasts, television, lectures and the distribution of literature. Your committee especially commends the activities of this bureau in regard to its program on physical fitness.

3. (*b*) Bureau of Medical Economic Research: Your committee approves the action of the Board of Trustees in the appointment of a well qualified director of the Bureau of Medical Economic Research. Reactivation and expansion of this bureau, especially in the field of economic research, should result in the accumulation of sound statistical information.

3. (*c*) Bureau of Exhibits: It was noted that the scientific exhibits at the recent meeting in San Francisco were outstanding, and your committee is exceedingly well pleased with the elaborate plans for the Scientific Exhibit at our forthcoming Centennial Celebration.

SUPPLEMENTARY REPORT OF THE BOARD OF TRUSTEES

1. Resolutions on Inclusion in The Journal of Important Medical Activities in Puerto Rico: Your committee is pleased to note that the important activities of the Medical Association of Puerto Rico are now included in The Journal in the section on domestic information together with the news from the several states.

2. Session on History of Medicine: A Session on the History of Medicine will be included in the Section on Miscellaneous Topics at the 1947 Annual Session. Should this session arouse sufficient interest, it is possible that a Section on the History of Medicine may be established at a later time.

3. Public Relations and the Rich Report: This entire matter has been acted on by the House of Delegates and warrants no further comment.

4. Resolution on Program of Health Legislation Beneficial to the People: In reference to this resolution passed by the House of Delegates at its meeting in December 1945 the Board of Trustees has accomplished much in stimulating medical legislation. (1) Although the President of the United States has not appointed a Secretary of Health and Welfare in his Cabinet, such designation has been urged; (2) representatives of the American Medical Association appeared at the hearings on the Kilgore-Magnuson Bill and presented suggestions for modification of the original measure, most of which were incorporated in the final bill which was passed by the Senate; (3) as a result of the passage of the Hill-Burton Bill, the board to administer this legislation has held several sessions to which representatives from the American Medical Association have been invited; (4) under the direction of the Board of Trustees, the development of Associated Medical Care Plans, Inc., has been accomplished. This will serve to coordinate all medical care plans; (5) the American Medical Association has now established a department of Public Relations and has expanded the Bureau of Health Education. All of the aforesaid activities are recommended by the resolution and have been carried out at the direction of our Board of Trustees.

In approving the report of the Board of Trustees in regard to its activities as detailed in the report for 1946 to date, your reference committee desires to record its deep sense of appreciation of all of the efforts of the Trustees in furthering the best interests of the American Medical Association.

Respectfully submitted,

Clarence G. Bandler, Chairman.
Edward P. McNamee.
Guy W. Wells.
James P. Wall.
L. J. Kosminsky.

Report of Reference Committee on Medical Education

Dr. J. F. Hassig, Chairman, presented the following report, which was adopted on motion of Dr. Hassig, seconded by Dr. George W. Kosmak, New York, and carried:

Resolution on Study of Child Health Service by American Academy of Pediatrics: Your committee recommends that this resolution be referred to the Council on Medical Education and Hospitals.

Respectfully submitted,

J. F. Hassig, Chairman.
A. W. Adson.
Leland S. McKittrick.
Alfred S. Giordano.
Henry B. Mulholland.

Report of Reference Committee on Miscellaneous Business

Dr. William A. Coventry, Chairman, presented the following report, which was adopted on motion of Dr. Coventry, seconded by several and carried:

Report of Judicial Council: There are seven main articles that have to be discussed in committee. All of them, however, have no great importance at this particular session. Therefore, your committee recommends that the report of the Judicial Council be referred for consideration at the next session of the House of Delegates.

Respectfully submitted,

William A. Coventry, Chairman.
R. B. Anderson.
George A. Woodhouse.
Warren L. Allee.
William F. Costello.

Motion on Dispersal of Federal Funds for the Control of Cancer

It was moved by Dr. Lowell S. Goin, California, seconded by Dr. Frank E. Reeder, Michigan, and carried, that the Council on Medical Service be directed to communicate with each of the constituent state associations urging them to place themselves in contact with those agencies which have under their care the dispersal of federal funds for the control of cancer, to the end that these funds may be administered wisely and with the cooperation of the practicing physicians of the several states.

Expression of Appreciation

Dr. George W. Kosmak, New York, moved that the House express its appreciation to the Speaker for his very effective conduct of this session.

The Vice Speaker, Dr. F. F. Borzell, assumed the chair.

The motion was seconded by Dr. H. B. Everett, Tennessee, and carried.

Motion to Adjourn

The Speaker resumed the chair.

On motion of Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, seconded and carried, the session adjourned at 12:30 p. m.

JOINT COMMITTEE FOR COORDINATION OF MEDICAL ACTIVITIES

MEETING OF COMMITTEE ON POSTWAR MEDICAL SERVICE, CHICAGO, OCT. 12, 1946

The Committee on Postwar Medical Service met on Saturday, October 12, in the Board of Trustees Room of the American Medical Association building in Chicago. The Chairman called the meeting to order at 10:03 a. m Members of the Committee and visitors present were:

Dr. Irvin Abell
Dr. Walter L. Bierring
Dr. Warren F. Draper
Capt William E. Eaton
Dr Morris Fishbein
Dr. Johnson F. Hammond
Mr Fred V. Hein
Dr. Elmer L Henderson
Mr. J W. Holloway Jr.
Dr. Hugo F. Hullerman
Dr. Ernest E Irons
Dr. Victor Johnson
Dr Edwin P. Jordan
Dr. B. R. Kirklin
Dr George F. Lull
Dr James M. Mason
Col. Hugo Mella
Dr. Carl M. Peterson
Lieut. Col. William N Piper
Rev A. M. Schwitalla, S J.
Dr. R. L. Sensenich
Dr. H H Shoulders
Mrs. M. V. Shuler
Dr. LeRoy P. Sloan
Dr. Dean F. Smiley
Lieut Col. John H Voegtly

ADOPTION OF MINUTES OF JUNE MEETING

The minutes of the meeting held June 8, 1946 (THE JOURNAL, October 19, p. 393) were approved as corrected

MEMBERSHIP

The Chairman announced that the Board of Trustees of the American Medical Association had appointed Dr R. L. Sensenich, South Bend, Ind, to succeed Dr. Francis G. Blake (resigned) as a member of the Association's committee He also announced that Lieutenant Colonel Voegtly had been designated as the representative of the Office of the Surgeon General, U. S. Army, in place of Col. Bryan C. T. Fenton, who has been reassigned. He stated further that Dr. F. S. Crockett, chairman of the American Medical Association Committee on Rural Medical Service, who had recently accepted liaison membership on this committee, finds it impossible to attend meetings and has resigned. Dr. Crockett was asked to name another member of his committee so that the problems of rural medical service can be included in the considerations of this Committee. (Dr. H. B. Mulholland, Charlottesville, Va., has accepted appointment as liaison member representing the Committee on Rural Medical Service.)

CHANGE IN NAME AND SCOPE OF COMMITTEE

The Chairman recalled to the attention of the Committee the discussion at the June meeting on continuance of the Committee and the desirability of a change in its name to indicate that the matters now considered are not purely "postwar" in nature but concern American medicine in general. He asked for expressions as to the sentiment of the organizations represented, stating that the Board of Trustees of the American Medical Association had expressed its desire that the Committee be continued. He also stated that the American College of Physicians had so expressed itself. Dr Abell, representing the American College of Surgeons, stated that he was sure that organization would be entirely agreeable. Dr. Bierring said that the Federation of State Medical Boards would like to see the Committee continued, and Colonel Voegtly was sure that the Surgeon General of the Army would desire its continuance. Father Schwitalla stated that the Catholic Hospital Association, which he represents, regards this committee as having done more than any other single agency to bring some order out of chaos. Captain Eaton stated that the Surgeon General of the Navy had expressed the thought that it would be an excellent idea to continue the Committee, and Dr. Draper said the Surgeon General of the Public Health Service also thought it desirable. Dr. Kirklin, representing the Advisory Board for Medical Specialties, was sure that the board would like the Committee to continue. The others present all agreed that the Committee should continue to be active

The Chairman then stated his opinion that the present name does not quite represent present deliberations, such as industrial health and physical fitness. After discussion the name "Joint Committee for the Coordination of Medical Activities" was adopted.

The Committee adopted a motion that the American Red Cross be requested to participate in the activity of this committee and that Dr. Draper be suggested as its representative. The Chairman said the Public Health Service would be asked to appoint another representative

BUREAU OF INFORMATION

The Bureau of Information is still receiving about one hundred letters a week from physician veterans, most of which concern locations The Bureau attempts to influence the men to locate in areas where they are most needed.

There was some discussion of the movement of physicians to new localities, and the question was raised of how information or statistics on the shift about the country might be obtained

SURPLUS PROPERTY

Father Schwitalla, Chairman of the Subcommittee on Surplus Medical, Hospital and Dental Supplies, reported briefly as follows:

> I have not had opportunity to follow up the many leads that were given at the last meeting. Within another month there should be a settling down, so that between now and the next meeting it might be possible to get out a report which might be valuable to the medical societies and to the hospitals and schools. As soon as the information becomes available, I think it should be presented to the subcommittee and, if its members agree, should be published immediately
>
> The surplus property people hope to open up the field more, and I hope that in the next two or three months something can be done to make the surplus property more available to schools

In the discussion Dr. Fishbein said that nobody is satisfied with the way the job is being done and that one serious difficulty is that the director has been changed at least five times Dr. Lull, Dr Henderson and Dr. Abell discussed unsatisfactory developments of which they knew personally, Dr Henderson mentioning a sale advertised to be held in Louisville to which about 400 doctors came from several states only to find they could not buy except in large quantities; all those doctors had to go back home without buying anything It was stated that the Surgeon General of the Army had recommended that all surplus medical supply and equipment be turned back to the original manufacturers and the manufacturers authorized to sell it at a stipulated price with a stipulated profit but that the War Assets Administration had refused permission because the U. S. Public Health Service did not want it done

A motion was adopted that the subcommittee prepare a final report on the surplus property situation and, if the subcommittee thinks it desirable, that the report be published as soon as ready.

INTERN AND RESIDENCY OPPORTUNITIES

Dr. Johnson presented the following statement

> As of today, Oct 12, 1946, there are 9,028 residency positions in 948 hospitals That figure is to be compared with the prewar figure in 1941 of just over 5,000 and shows an overall expansion of from 5,256 to 9,028 As to individual fields: In 1941, in anesthesiology there were 121 positions; now there are 268. In internal medicine there were 803, now 1,393, not quite double. In obstetrics and gynecology 442 before the war and now 768 Orthopedic surgery rose from 194 to 440, pediatrics from 393 to 589, psychiatry from 423 to 767, radiology from 250 to 485 and surgery from 900 to 1,663. The expansion has been rather general and of about the same magnitude in all important fields. The vast majority seem to want training in general surgery When the original estimates were made as to the number of residency places that probably would be needed, it was thought there ought to be approximately double the 1941 number, but that was based on the belief that it would take two years from V-E day for medical officers to be discharged; most were discharged within a year. We now have an increase of 70 per cent in residency positions, which indicates that the hospitals and agencies involved are doing very well, and the number is still expanding. A large number of applications for approval continues to be received

There was lengthy discussion, during which Dr. Johnson was asked and replied to questions as follows:

> How near is supply and demand now balancing? The best criterion we have here is the number of requests received; that has tremendously decreased in recent months

Are the 9 000 residencies all filled? Virtually all are filled

What is the present status of residencies in veterans' hospitals? Very few so far have been formally approved Those residencies will be considered exactly in the same way as other residencies More requests are being received and it is hoped that more and more will be approved

The standards of residency training may have been lowered in some instances, how soon can the demand be filled and the standards raised again? I think the peak will be passed within a year or two and I think we should look forward to reducing the number of residencies from 9,000 to perhaps 6 000 or 7 000 Much of the reduction will be in the nature of the reduction of the number of men in a given residency However the number of institutions participating has increased from 610 to 948 It is probable that later on approximately 200 of those hospitals should be removed from the list

What about the army and navy hospitals? How many are approved? An appreciable number of navy hospitals and some army hospitals have been approved (Colonel Voegtly said The army general hospitals are being approved for extension of residency training, at present there are ten hospitals in that program Captain Eaton stated that eight navy hospitals are now approved by the specialty boards, all the navy hospitals provide internships and consultation boards of civilian specialists assist with training teaching and the like, the program is being pushed along very fast there are about 27 000 patients at home and abroad)

What is the attitude of the specialty boards relative to these residencies approval of which may be discontinued? Are they accepting all of them? A hospital is not placed on the approved list unless the appropriate specialty board concurs

Is it not true that approximately 7 000 graduates now interning will enter the service and that when they come out, by the time the present residents finish there will still be a surplus and a peak after more than a year? I agree with you that the emergency will not be entirely over and the situation back to the prewar status within two years (Colonel Piper said that 14,749 medical officers were discharged as of Oct 5, 1946)

Dr Shoulders thought that the discontinuance of the approval of lots of hospitals at an early date should not now be discussed, since the men who have been discharged now have the priorities and there is a large number of men graduated within the war period, last year and now, who are up for assignment to internships and residencies

Father Schwitalla agreed that if an increased number of present medical students is added to the veterans who are seeking residencies the sum is going to be larger within the next year or two even than in the past He said that it is, however, a bad sign for this curve of residencies to rise

Dr Johnson stated that the hospitals certainly would continue to be encouraged to develop programs and such programs would not be contracted at a more rapid rate than is warranted by the demand

The Chairman made the following observations We are struggling with a difficult problem I think it is splendid that we have such a problem It means that the standard of medical education will continue to rise That is a great contribution of the specialty boards There are a number of hospitals that have been approved on recommendation of the specialty boards and the Council on Medical Education and Hospitals which probably would not have been approved for a long time had inspection been possible If those hospitals can be stimulated to justify their approval, this will provide further improvement in the quality of hospital service

It was Father Schwitalla's opinion that some hospitals are going to improve rapidly but, by the same token, the possibility of some to reach a high level is going to be reduced because there is a tendency among medical students to look for their internships in hospitals where they ultimately expect to have residencies, they want a chance of getting that residency, and they think the hospitals are going to choose from their own staffs, most of the larger hospitals are giving their residencies to their own interns and that has a tendency to put the less desirable medical students into the less desirable hospitals, thus there is a raising of the internships and residencies in the better hospitals but there is a deterioration in the smaller hospitals because they are less desirable for the intern

Dr Johnson's report was accepted with appreciation

THE RESIDENT PROGRAM FOR PHYSICIAN VETERANS

Father Schwitalla chairman of the Subcommittee on Graduate Education of Physician Veterans presented the following report

1 A Report of Progress

Dr Victor Johnson and the chairman of the subcommittee agreed to attempt the formulation of a report of progress of the program authorized by the Veterans Administration of securing graduate medical education for physician veterans acting as residents in approved hospitals A letter was sent on September 24 to the deans of the schools of medicine asking [illegible] to express themselves if they so chose concerning the success of the resident education program or phases of other education programs in medicine under the Veterans Administration

Thirty seven schools of medicine in the United States and five in Canada replied All the Canadian schools acknowledged the letter but recognized that the problem was one pertaining to the schools in the United States only

2 General Comments

It is obvious from the letters of the deans that the program of graduate education through residencies in hospitals for physician veterans is meeting the favor of the deans Sixteen schools explicitly stated that the plan is operating satisfactorily and seven others stated that the plan is regarded as satisfactory but is nevertheless deserving of some criticism Ten of the schools emphasized their adverse criticisms without expressing commendation and four schools stated that they had no program

The criticisms and suggestions which were received in the thirty seven letters might be grouped under five headings, criticism of (*a*) policies (*b*) the financial arrangements (*c*) entitlement of veterans to educational benefits (*d*) the personnel of the Veterans Administration and (*e*) procedures Under each of these five headings there is at least one outstanding common difficulty mention of which recurs in a number of the letters

With reference to policies it is pointed out by a majority of the writers of the letters that confusion exists concerning the interpretation of the law and of the regulations It is pointed out that in different sections of the country different interpretations prevail Apparently the local offices of the Veterans Administration are thought not to be in sufficiently close contact with the Washington office to ensure uniformity in policy making and uniformity in administration It would seem too that in at least 1 case which was discussed in detail, there is suspicion of broken faith, at least so the institution interprets the demand by the Veterans Administration for a renegotiated contract after the institution has committed itself to the expenditure of funds involving possibly a $25,000 deficit

With reference to the financial arrangements, the outstanding problem is the amount of the payment which is due to the school of medicine or to the university authorities as tuition for the resident veteran physicians Some of the schools are receiving $500 tuition but in all cases that have been revealed by the recent correspondence the residents are regarded as students in the university, sometimes under the graduate school and in other instances under the school of medicine, and the tuition is paid not so much for the residency as for the regular courses even though the education includes the usual functions and duties of the resident

There is a general demand in the correspondence for the authorization of a $500 tuition payment Perhaps this subcommittee should recommend to the Committee on Postwar Medical Service that, wherever possible, the resident should be registered in the graduate school or in the school of medicine in order that the Veterans Administration may be able to pay the $500 tuition to the institution without going through the elaborate formality of writing a contract, as is provided for in the present regulations

Growing out of this situation is the further one that in some areas the Veterans Administration has permitted the use of funds in an amount represented by the difference between the $500 per year maximal allowance and the $180 paid as tuition in whole or in part for the purchase of books, instruments and supplies Practices with reference to this are by no means uniform

With reference to entitlement, the central problem seems to be the interdependence of the subsistence allowance paid to the veteran physician and the tuition payment paid to the school or hospital When tuition payments and other school expenses exceed $500 a year, the veteran may choose to have all his school expenses defrayed by the Veterans Administration but in making that request he shortens the period of his entitlement and at the same time deprives himself of further subsistence Several of the letters regard this as a serious defect in the program

With reference to the personnel of the Veterans Administration, the complaint is made that serious difficulty has been encountered in dealing with the officials of the Veterans Administration, who are said at times not to understand educational terminology or many of the phases of school administration and particularly of the administration of schools of medicine Some of the deans complain that training officers are changed too frequently Scarcely have they succeeded in establishing relationships with one training officer before he is moved, and another must be trained

Complaints are rather general that the procedures of the Veterans Administration are unnecessarily involved that there is too much paper work too many blanks too many diverse interpretations of the same blank and, finally, that too long a time elapses between the filing of claims or bills and the payment made to the schools In this connection one serious difficulty is pointed out, namely, that the Veterans Administration pays only at the end of the semester and that the school's regulations regarding the prepayment of tuition at the beginning of the semester is not being carried out by the Veterans Administration

3 Criticisms and Suggestions

A Policies

1 Uniformity of policies is highly desirable throughout the country

2 Much confusion exists concerning diverse practices and policies

3 The Veterans Administration in some localities objects if charges are made against the Veterans Administration when no charges are assessed against civilian residents

4 The pressures against the hospitals from the residents the staff members, the Veterans Administration and the medical schools seem to have forced some hospitals into questionable misrepresentations of their programs

5 Interest in refresher courses is lagging Attention should now be directed to the attitudes five years hence when these physicians who have failed to take advantage of the educational opportunities of today will recognize their mistakes

6 If the Veterans Administration exposes itself to the charge of arbitrarily modifying or canceling contracts as seems to have happened in one instance it will seriously jeopardize the success of its own program

7 Hospitals which increased their number of residents to assist in what was represented as a national obligation now feel aggrieved, and many of them are in serious financial difficulties as the result

B FINANCIAL

8 The amount allotted to students and the universities or hospitals does not cover the expenses of the student nor of the educational institution

9 There is a fairly general demand that something should be done to secure a $500 tuition payment for each resident receiving his graduate education in a university hospital The Veterans Administration should be asked whether it cannot recognize all of these residents as graduate students in the university

10 The ceiling of $200 which in some localities is about to be established in accordance with new rulings will undoubtedly disrupt the plan now in operation The Veterans Administration must remember that physicians as a class are 10 years older than the average G I

C ENTITLEMENT

11 Dissatisfaction is growing concerning the procedure of shortening the period of entitlement if in any one year the student's expenses exceed $500

12 The provision that a school may not charge the veteran unless a similar charge is customarily made against other residents needs interpretation

D PERSONNEL

13 Difficulty has been encountered in fitting the terminology of the Veterans Administration's educational directives into the customary university and school of medicine patterns, in interpreting the differences between the various kinds of educational experiences in colleges, etc, as contrasted with those of a school of medicine, in interpreting the differences between the courses of the undergraduate curriculum and the courses of a resident program

14 The Veterans Administration program has had a serious effect on the psychology of the residents, making it difficult to reconcile the attitude of the veteran with that of the physician

15 The training officer is changed too frequently, making it impossible to establish consistent policies in the institution

E PROCEDURES

16 The delay in negotiations and the subsequent delay in securing payment has been very burdensome

17 The paper work to be done may be thought to be unavoidable by the Veterans Administration, but it is a source of resentment to some of the schools of medicine

18 There must be some way of simplifying procedures

19 Several of the blanks should be simplified and the whole series of blanks used by the Veterans Administration in dealing with the residents should be harmonized

20 Even after six or seven months of experience with residents, some hospitals have received no pay

21 The Veterans Administration's policy of paying tuition only at the end of the semester throws too much danger of a loss of tuition on the school The Veterans Administration should be held to observe the school's regulations concerning tuition payment

22 The interdependence of subsistence allowances and payments for educational costs may work serious and perhaps avoidable hardships either to the university or to the student in some cases

During the discussion it was brought out that the A S T P and V-12 student is not entitled to educational benefits under the G I bill, since he is not considered a veteran unless he has actually served with troops for a certain length of time ninety days' service outside the A S T P or V 12 It was stated that some students delayed their discharge and on their terminal leaves went with the troops, thus becoming entitled to G I benefits

The Chairman restated an amended motion that the Joint Committee commends in highest terms the efforts of the Subcommittee and particularly its chairman, Father Schwitalla, in formulating its report, and further instructs the subcommittee to proceed as may seem desirable in bringing this matter to the attention of the proper section of the Veterans Administration to the end that the whole situation may be clarified, and that Father Schwitalla be commended for his action at St Louis University School of Medicine, of which he is dean The motion was duly seconded and adopted unanimously

LICENSURE

Dr Bierring presented the following statement

In bringing the attention of the Committee on Postwar Medical Service to certain matters pertaining to the licensing of returning medical officers and relocation, there are two factors to be mentioned First is the feeling on the part of the officer that because of his experience he is entitled to certain privileges which in some instances are not reasonable and not permissible because of legal restrictions Secondly I think that in a general way boards of examiners have endeavored to be as liberal as possible

One difficulty giving great concern is the basic science examination There are now eighteen basic science boards, their original purpose was to determine whether or not a man had knowledge enough to be admitted to examination for the practice of the healing arts The basic science examination has gradually evolved into practically the same as that required in regular medical examinations The result is that there is a growing tendency for basic science boards to assume more importance in connection with the licensing of physicians The difficulty is that only four of the basic science boards have reciprocal agreements with one another Six accept the grades of the National Board of Medical Examiners two accept other grades or the grades of licensing boards or of any properly authorized examining board several require not only an average of 75 per cent but also a minimum grade of 75 per cent in each of the basic sciences concerned A committee composed of representatives of the Federation of State Medical Boards and of the basic science boards has been appointed and it is possible that that committee may be able to work out some solution

Graduates of unapproved schools constitute another difficulty—how to analyze the value of their military service The need of the community in which they wish to practice also enters into the picture The fact that the New York State Board of Medical Examiners has been accepting some of these graduates makes for confusion in reciprocity licensure

The foreign graduates are also a problem, especially the graduates of the extramural schools of Great Britain, not any of which are connected with the universities In 1939 most of the licensure agencies and also examining boards and the National Board of Medical Examiners took action that they would not accept for examination any person who enrolled in any of the extramural schools after July 1, 1939 About 300 were stranded in Great Britain at the beginning of World War II A considerable number who graduated before 1939 or were students in 1939 were admitted to examination in New York State, where there was a liberal tendency some years ago to admit foreign graduates to examination Now these men have had military service or are anxious to locate in some other state, and it is difficult for the examining boards to determine their eligibility At present representatives of the General Medical Council and the Council on Registration of the United Kingdom are visiting in the United States to consider this problem Other foreign medical graduates came from Italian schools Again, the New York state board permitted many of these to take the New York examination and admitted them to licensure Many have now had military experience and because they passed the New York state board and because of the need of the local community, many states have accepted them There is the same difficulty with respect to graduates of medical schools of Spain, particularly of Barcelona It is difficult to obtain any kind of records even of their graduation A conference of the various agencies concerned has been called to meet in February to decide the problem of the foreign medical graduates This whole matter is concerned with the need for physicians, particularly in rural areas

The Chairman thanked Dr Bierring for his report

SPECIALTY BOARD FOR GENERAL PRACTITIONERS

At the conclusion of his report, Dr Bierring raised the question, for discussion, of the future of the general practitioner He said The general practitioners perform 85 per cent of all the practice, something should be done to stimulate them with the same stimulus that is given to the specialists, if the needs of the rural physicians are to be met, something must be done to dignify them in some way or another, the American Medical Association has set up a special scientific section on general practice, why cannot there be a specialty board to give these men recognition as general practitioners? Their training should be commensurate with the part they play

Dr Kirklin explained that it is not the function of the Advisory Board for Medical Specialties to create new specialty boards but merely to accept applications and to advise Dr Henderson thought it might be a good thing if the Section on General Practice of the Scientific Assembly of the American Medical Association would present a resolution to the Association's House of Delegates urging that such a step be taken Dr Kirklin thought that the general practitioners should be given some such recognition, citing the fact that most hospitals are demanding certification of their staff members, which, having no certification of any kind tends to prohibit the general practitioner from doing surgery in the hospitals, which he feels he is qualified to do

Mention was made of the Indiana Board of General Practice of Medicine, recently established on authorization of the Indiana State Medical Association to grant and issue certificates of qualification to candidates successful in demonstrating their proficiency ' as general practitioners

Dr Bierring said that at one time the National Board of Medical Examiners had considered the advisability of the establishment of a specialty board but had decided there were too many difficulties involved He thought the National Board might now be more inclined to foster the matter

The Chairman asked Dr. Bierring, Dr. Kirklin and Dr. Sensenich to prepare a report on the subject for presentation at the next committee meeting.

ESTABLISHMENT OF MEDICAL CORPS IN VETERANS ADMINISTRATION

Father Schwitalla, chairman of the Subcommittee on Establishment of a Medical Corps in the Veterans Administration, asked Colonel Mella for a comment, and he made the following remarks:

> You probably all know that a bill was passed and signed by the President—Public Law 293 The Department of Medicine and Surgery has been organized under that law and is now operating There are still many phases to the reorganization which require further development, but definite progress has been made. The bill submitted did not pass in its original form It was necessary to accept certain modifications in order to get some sort of bill which would give the department a free hand in the selection of physicians, dentists and nurses, which we now have I would suggest that the Committee give consideration to the possibility of continuing the sub committee

RURAL MEDICAL SERVICE

In the absence of Dr. Crockett, the Chairman asked Mrs Shuler of the Association's staff, who has been assisting Dr. Crockett in the work of the Committee on Rural Medical Service, to tell the Committee something of the plans for the second National Conference on Rural Health, which is to be held in Chicago in February. Mrs Shuler gave a résumé of the proposed program for the conference, saying that it had been planned at a recent meeting between the Committee on Rural Medical Service and representatives of farm groups She further stated that it is hoped to have the conference as informal as possible

The Chairman thanked Mrs Shuler for her presentation and said the item would be on the agenda for the next meeting

INDUSTRIAL HEALTH

Dr Peterson spoke to the Committee as follows.

> The House of Delegates of the American Medical Association at San Francisco in July approved a proposal that the advancement of industrial health activity should be a cooperative affair between management, labor and medicine. This was considered at the Annual Congress on Industrial Health held a few days ago in Boston. One suggestion for its implementation was that a physician having the labor point of view might be included in the membership of the Council on Industrial Health Another suggestion was that some sort of Joint Conference Board be set up and on that board there be representation from management and labor groups Past experience leads us to feel that we can arrive at a satisfactory way of working out these matters There are areas of agreement rather than of disagreement. A third suggestion was that the Council become better informed regarding the actual medical services that are being formed and developed by the labor groups themselves. Some are doing good work, others not so good Our relations with management have always been cordial. Out of that has grown a practical problem in professional relations which has to do with the medical veterans' question as well Some of these men are attempting to set up services for small industrial plants. They are asking us "Assume that we set up a clinic or offices in an industrial area, what is the ethical position as to our soliciting industries in the area?" We took the position that they ought not to solicit, and the Judicial Council of the American Medical Association agreed. Now we are getting around to taking the position that, if agreeable to the county medical society concerned, the physicians can go out and let industries know that the services are available. If we do set up relations between management, labor and medicine, it will be difficult to hold the discussions to the realm of industrial disability What cooperative relationships should we set up within the Association itself when we begin to bring this procedure into effect?
>
> Another development of importance is the decision on the part of the Council on Medical Education and Hospitals to review graduate training in the field of industrial medicine. Efforts have been made to establish a certifying board, but one of the big obstacles is that we do not have an educational program comparable to what has been set up in the other special fields Advances have been made to the Council on Medical Education and Hospitals to see if we may not take a leaf out of the experience of the other specialty boards and set up a residency program Although it probably would be impossible to approve a department in an industrial plant as an educational institution, the apprenticeship experience should be had in an industrial medical department

Dr. Bierring asked if the creation of a certification board would not be furthered by the establishment of schools of industrial health and in that way a form of specialist service would be developed and standards set. Dr. Johnson thought the people in industrial medicine are proceeding wisely, and Dr. Kirklin said that application for a certifying board has been made.

Father Schwitalla asked if the Student Health Association had not tried to set up a residency in student health services as a part of the residency in internal medicine and was informed—and most of the members agreed—that that had been discussed by the American Board of Internal Medicine but, because of the quality of procedures in most student health departments in universities and schools, it was felt that such action was unwarranted

Dr. Peterson's statement was received with appreciation

PHYSICAL FITNESS

The Chairman introduced Dr Dean F. Smiley and Mr Fred V Hein, who have recently been added to the staff of the Bureau of Health Education of the American Medical Association to conduct a Health and Physical Fitness Project under the supervision of the Association's Committee on Health and Physical Fitness. In his introduction the Chairman stated that by including this project in the total health education program of the Association and staffing it with a physician who has had wide experience in health education and an educator experienced in the health and physical education fields it is given a permanence and *practicability lacking in* the previous organization

Dr. Smiley presented the following:

> The Health and Physical Fitness Project will include the health and fitness problems of the preschool child, the school child, the college student, the adult, both rural and urban, and the industrial worker. Though the committee contemplates cooperation with all other health agencies working toward health improvement in home, school, industry and community, it has expressed the belief that it is first in the schools and second in industry that the most immediate and most practical approach to the problem lies. No attempt will be made to set up any master plans or "ideal" health programs and then to procure their widespread adoption in schools and industries of all types and sizes. Rather it is the plan to accumulate source files on the varied health programs now in use with the purpose of making both reports on these programs and the advice and counsel of Mr. Hein and myself available on invitation to boards of health, boards of education, employers, employee groups, medical societies and women's organizations
>
> This project is in a sense a continuation of the work carried on by the American Medical Association in conjunction with government agencies and other interested groups during the late war

Mr. Hein gave further information on the project, as follows:

> On September 17 Dr. Smiley and I met with the Committee on Physical Fitness, which more or less outlined the things it would like to have done We have gone ahead with that plan The approach which seemed most logical was primarily through the schools, at the secondary and elementary levels particularly. We have begun a source file, have drawn on the resources of the previous committee and are gathering additional material The first series of thirteen electrical transcriptions on physical fitness will shortly be ready Visits for consultation with educational and medical groups have been arranged A television program is contemplated We hope to expand the program greatly as time goes on.

The Chairman asked Dr. Smiley and Mr. Hein to be present at the next meeting and give a further report

AUTOMOBILE PRIORITIES FOR PHYSICIANS

The Chairman presented a resolution on automobile priorities for physicians, which had been referred to the Committee on Postwar Medical Service by the House of Delegates of the American Medical Association He said that the House of Delegates had approved the resolutions in principle. After extended discussion the matter was laid on the table.

CORRESPONDENCE

Dr Shoulders said he had received a number of letters from men in the regular Navy Medical Corps who have not been allowed to resign. It appears, he said, that most such men had taken their intern training as members of the Reserve Corps and, on completing it, had been offered commissions in the regular Navy with the assurance that they would be allowed to resign on the same basis as the Reserve Corps but actually were not allowed that privilege He asked Captain Eaton to explain the matter, if possible, so that he might reply to such communications correctly.

Captain Eaton replied as follows: The Navy now has 3,700 doctors, of whom 1,900 are members of the regular Navy Medical Corps. Something over 4,000 are needed—between 4,200 and 4,500. At present there are approximately 500 at sea and about 800 at overseas bases, and there are 2,400 in the continental limits. There are about thirty-six or thirty-seven hospitals in operation and about 27,000 patients overseas and at home. Those men who were in the V-12 program and got their medical education thereby are being retained for about two years after they have completed their internship and are ready for service. A sincere attempt was made to get some of the Reserve officers, the younger men, to transfer to the regular Navy, but it was not very successful. Most of those who transferred were older men who did not want to go back to private practice. Many of them were rather well qualified men whom we could use in the residency and intern training program to advantage. The problem has been very difficult for the Bureau of Medicine and Surgery to handle, trying to maintain enough Navy medical officers to carry on the work. As I have said, there are 1,900 regular Medical Corps officers altogether; the number of regular officers required by the Navy was set at 4,500, 2,500 lacking. In the endeavor to get men who had been in service to fill up this vacancy, the Bureau wrote letters such as those presented by Dr. Shoulders. There now is a law authorizing the transfer of officers from the Reserve into the regular Navy; when the letters were written, there was no such law. Now a Reserve officer can be transferred to the regular Navy by applying and, if the Bureau and the Surgeon General consider him qualified, he is commissioned. I think the only thing that can be said in reply to such communications is that as an officer of the regular service, the policy of the Navy Department today is that resignations will not be accepted until such time as the officer's services are no longer required to meet the emergency. Reserves ordinarily do not resign; they are placed on inactive status. A man in the regular service has signed an oath to stay, and he has to conform to the policy of the Navy Department.

Dr. Draper said: The Public Health Service established a point system whereby they would release Reserve officers, but it did not apply to the regular officers; in the course of time the regular officers became dissatisfied, and they are now on the same basis; that resulted in the loss of approximately 100 regular officers from July 1 to September 1; unlike the Navy, the Public Health Service does have some work not concerned with the actual care of patients, and its effort was to contract in certain lines and to close some hospitals.

In reply to a question by Dr. Shoulders, Captain Eaton said he understood that a fairly satisfactory number of applicants for commissions in the regular Navy Medical Corps are being received.

COMMUNICATION FROM MISS SWITZER

The Chairman read a letter received from Miss Mary Switzer, liaison member of the Committee representing the Federal Security Agency, as follows:

> One of the problems which has come to my attention in the last couple of months since the last meeting of the Committee is the difficulty that young men coming back from service are having in securing staff appointments to hospitals. You may remember that our committee touched on this subject once or twice within the last year. I believe it was brought out that the pressure for hospital beds is so great in many communities that one has to be on the staff of a hospital to get a patient into one. This naturally makes the men on the staff reluctant to extend staff facilities to more physicians than the bed capacity warrants.
>
> I can see that it is a vicious circle, but I think we should also be aware that the men coming back from overseas, particularly the younger ones who have not had an opportunity to make their connections, could become very discouraged, if not bitter, if this situation is allowed to become acute.
>
> I wonder if you could bring this up before the Committee and see whether other members have had evidences of this situation and whether any suggestions can be made to ease the strain. It is particularly acute in some of our smaller cities. I am not sure whether it is so serious in large ones, although I believe Chicago is one of the places from which complaints have come to me.

The Chairman was of the opinion that this committee could do little to remedy the situation except perhaps to urge the hospitals to consider the needs of the veteran physicians.

DATA ON ARMY SEPARATIONS

Colonel Voegtly presented the following figures on army separations as of Oct. 5, 1946:

Medical Corps	260	Total separated	44,749
Dental Corps	82	" "	13,346
Nurse Corps	111	" "	48,470

TIME AND PLACE OF NEXT MEETING

It was decided that the next meeting, which will be the first meeting as the Joint Committee for the Coordination of Medical Activities, will be held at American Medical Association Headquarters in Chicago on Jan. 11, 1947.

Official Notes

ATLANTIC CITY SESSION

Scientific Exhibit—Applications Close January 13

Applications for space in the Scientific Exhibit at the Atlantic City Session close on Jan. 13, 1947. Prospective exhibitors are urged to submit their applications for space immediately, since applications received after the closing date are placed on the waiting list to be considered only if space becomes available. Applications for a place on the motion picture program in the Scientific Exhibit do not close until February 15, but those applications should be submitted as early as possible also.

Application blanks may be obtained from the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10.

DEATH OF CHARLES MOHLER

Mr. Charles S. Mohler, Assistant Business Manager of the American Medical Association, died Dec. 23, 1946 in a hospital in Elkhart, Ind., following an automobile accident which occurred two days previously. Mr. Mohler had been employed at Association headquarters in Chicago for about thirty years.

Washington Letter

(From a Special Correspondent)

Dec. 23, 1946.

Public Health Service Seeks New Medical Research Center

The 80th Congress, which will convene on January 3, will be asked by the U. S. Public Health Service for funds to establish an extensive new medical research center as part of the National Institute of Health in Bethesda, Md. Included in the 15 to 20 million dollar center would be a two hundred to three hundred bed hospital for clinical study and treatment of cancer patients. A similar section would be devoted to the study of aged patients and those with heart diseases. The service also plans to ask Congress to appropriate more than $5,000,000 for the expansion of clinical and laboratory cancer research. The total appropriation at present is $1,772,000. Most general hospitals now function as treatment centers and have few facilities for research, while the National Institute of Cancer must confine its work to research and send scientists to other hospitals for clinical work, it was explained.

Hawley Stresses Need of Private Hospitals in Veteran Care Program

Major Gen. Paul R. Hawley, medical director of the Veterans Administration, told a luncheon club here that the American people must decide if the agency is to give complete medical care to all veterans. He explained that the present medical care program is primarily for those with service connected disabilities but that vacant beds in veterans' hospitals may be occupied by veterans with non-service connected ailments, provided the veteran is not financially able to pay for private medical care. If the Veterans Administration medical service is to apply to all veterans for any disabilities, General Hawley said that the agency's medical department will have to be revised and greater use will have to be made of private hospitals. He explained that such a medical program could "never succeed under a full time medical service in government hospitals—it can only be kept at a proper standard through the use of the best private hospitals in the country." Veterans Administrator Omar N. Bradley has ordered a radical change in long-standing policy to provide more hospital beds for veterans. Henceforth, non-service connected patients with diseases or disabilities requiring medical treatment rather than hospital care will be placed "on leave" from the hospital and thereafter given what amounts to outpatient care. Savings in the patients' time and hospital bed space is expected to be considerable, under the new policy, in cases of heart conditions, arthritis, cancer, diabetes, skin infections and dental care.

Treatment of Leprosy

The Advisory Committee on Leprosy in the United States met at the U. S. Public Health Service Building here in an all-day session and heard reports on current methods of treatment and control of leprosy or Hansen's disease. Officials reported that a sulfonamide drug, Promin (sodium p,p′diaminodiphenylsulfone-N,N′-didextrose sulfonate) has been used successfully at the National Leprosarium at Carville, La., in arresting the disease. Thirty-eight per cent of 137 patients treated with the drug during two years showed a reversal from positive to negative in bacteriologic tests. Other sulfonamide drugs, Promizole (4,2′-diaminophyl-5′-thiazolylsulfone) and diasone (disodium formaldehyde sulfoxylate diaminodiphenylsulfone), are said to have shown promise. Dr. Thomas Parran, Surgeon General of the service, revealed that the disease occurs mainly in the Gulf Coast states and is "a public health problem of continuing importance."

One Hundred and Twenty-Five Army Medical Officers to Be Released to U. S. Public Health Service

The War Department has announced that one hundred and twenty-five Army medical officers who are not classified as specialists may apply to serve their active duty as members of the U. S. Public Health Service. The action was taken to assist the public health service through a "difficult period," it was explained. Regular Army officers, those listed as specialists, and physicians who have volunteered to serve as long as twenty-four months are excluded from the transfer. The department also reminded wartime officers who have returned to civilian life that December 31 is the closing date for applications for Regular Army commissions.

Commentators Fear Production of Motion Pictures Glamorizing Use of Drugs

Fears that relaxation of the code of the Bureau of Narcotics to permit the making of films depicting drug addiction would result in a cycle of movies with drug traffic plots were expressed by the Catholic National Legion of Decency and others here. The code was amended to read: "Illegal drug traffic must not be portrayed in such a way as to stimulate either curiosity or interest concerning the use of, or traffic in such drugs, nor shall scenes be approved which show the use of illegal drugs or their effects in detail." The Legion of Decency stated that this provision "in effect opens the door for the production" of drugs films, and "reports indicate that several companies are planning 'dope' production."

Walter Reed Patients View Film Depicting Home-Coming Problems of Amputee

A former Walter Reed patient, Harold Russell of Cambridge, Mass., was one of the stars of a new Goldwyn film, "The Best Years of Our Lives," depicting home-coming problems of veterans, one an amputee, which was screened for other patients at the hospital. The only previous showing was to General Eisenhower and War Department and Veterans Administration officials.

National Committee for Employment of Handicapped

Major Gen. Erskine, M. C., U. S. Army, was elected chairman of a permanent National Committee for Employment of the Handicapped at a meeting held in the Smithsonian Institution and attended by representatives of over one hundred groups. More than three hundred organizations will participate in the committee, which will seek to promote employment of both civilian and veteran handicapped through a national educational program.

Council on Medical Service

MEDICAL CARE PLAN NEWS

Louisiana Physicians Service, Inc., the prepayment surgical and obstetric care plan sponsored and approved by the Louisiana State Medical Society, reported encouraging enrolment results in its first month of active enrolment. During the month of November, 1,567 certificates were issued covering in excess of 4,850 persons. The enrolment figures are reported from three of the four branch offices in operation in November.

The home office of the company is at 1430 Tulane Avenue in New Orleans. Branch offices are operating in the cities of Baton Rouge, Alexandria, Shreveport and Monroe. Blue Cross hospitalization enrolment facilities are used in the first two branch offices, and facilities of an independent nonprofit hospitalization group are used in the latter offices.

The plan was incorporated on Aug. 18, 1946 under the Industrial Insurance Laws of the State of Louisiana (particularly act 148 of 1936, as amended) as a mutual nonprofit insurance company. The company received its Certificate of Authority to operate in Louisiana on Sept. 30, 1946.

A surgical benefit certificate is issued to each subscriber providing an indemnity coverage to each enrolled person for surgical and obstetric care, including treatment of fractures and dislocations, and also provides for coverage for certain related benefits for diagnostic x-ray, anesthesia and laboratory service.

The plan is in the process of enrolling a panel of participating physicians who will accept the indemnity as provided in the Schedule of Benefits as full payment for service for persons whose annual income is less than $2,000, if single, and for the family group whose aggregate annual income is less than $3,000. Approximately 30 per cent of the physicians in Louisiana have enrolled as participants in the plan with the area of Shreveport reporting approximately 65 per cent of the physicians participating. Physician participation is increasing daily.

The plan is doctor controlled, having a board of directors of ten physicians and one lay member. Directors are chosen from a board of trustees selected by the Louisiana State Medical Society. The plan also bears the endorsement of the Council on Medical Service of the Louisiana State Medical Society. Officers of the company are O. B. Owens, M.D., Alexandria, president; William L. Bendel, M.D., Monroe, vice president; H. Whitney Boggs, M.D., Shreveport, secretary-treasurer, and Frank Lais Jr., New Orleans, executive director.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 10-11. Dr. Victor Johnson, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Orthopedic Surgeons, Chicago, Jan. 25-30. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.

Central Surgical Association, Chicago, Feb. 20-22. Dr. Walter G. Maddock, 250 East Superior St., Chicago, Secretary.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24-27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary,

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Southeastern Allergy Association, Atlanta, Ga., Jan. 18-19. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 49, S. C., Secretary.

ARMY

MEDICAL BUILDING PROGRAM FOR 1947

The War Department has authorized army engineers to initiate the fiscal year 1947 army construction program for the continental United States at a total estimated cost of $60 069,752 This program has received approval of the Office of War Mobilization and Reconversion The housing program accounts for $41,329,500 of the total

The Army s construction program for the Medical Department is as follows

Percy Jones General Hospital, Battle Creek, Mich , thirty-six housing conversions and elevator repairs, $100 000 , physical therapy facilities, $2 500

Letterman General Hospital, San Francisco, twelve housing conversions

Fitzsimons General Hospital, Denver, twenty housing conversions

Madigan General Hospital, Tacoma, Wash , twelve housing conversions

William Beaumont General Hospital, El Paso, Texas, twenty-eight temporary housing units

Oliver General Hospital, Augusta, Ga , conversion of wards for care of neuropsychiatric patients, $287,000

Fort Totten, New York, establishment of medical laboratory, $200 000

Walter Reed General Hospital, Washington, D C , eight temporary housing units, postoperative recovery ward, $70,590

FOOD SERVICE SUPERVISORS

A new category of thoroughly trained army staff officers whose sole duty will be the supervision and direction of the food program of their command has been established, the War Department has announced The special food officers, to be known as 'food service supervisors," will be assigned to army commanders at all echelons from battalion to overseas theater and will range in rank from first lieutenant to lieutenant colonel Simultaneously a new class of enlisted personnel to be known as food service technicians" and ranging in rank from corporal to master sergeant has been established These new categories will not increase the authorized basic troop strengths Their objective is to improve the standards of the army subsistence program as recommended by a nine man committee of civilian experts In general the food service supervisors will closely watch the food program of their organization always with the view toward improvement of service, health of the men, variety and elimination of unnecessary waste

Officers selected for the duty will have a thorough knowledge of procurement, storage distribution, preparation and service of food Enlisted personnel selected for assignment as food service technicians must also meet high standards In general they must be high school graduates or equivalent, and meet high mental, health and training requirements

ANNUAL PHYSICAL EXAMINATIONS

The annual physical examination for regular army officers, reestablished for 1947, has been expanded to include all officer personnel of the Army nurses, ward officers, warrant officers and flight officers, as well as retired officers on active duty The War Department circular points out that certain categories of officers are not required to take the examination, including those who undergo a final type examination subsequent to Oct 1 1946 in conjunction with integration into the regular Army.

ARMY AWARDS AND COMMENDATIONS

Colonel Austin J. Canning

The Oak Leaf Cluster to the Legion of Merit was recently awarded to Col Austin J Canning of Bethlehem, Pa The citation stated that during the war Colonel Canning organized and operated Rhoads General Hospital, Utica, N Y , to provide the highest quality of medical care Through outstanding ingenuity he considerably increased the hospital's bed capacity and to combat shortages in medical department personnel, explored, promoted and trained volunteer women's units He supervised the training of numerous medical units, inspiring them by example to devotion to the welfare of the sick and wounded Dr Canning graduated from the University of Pennsylvania School of Medicine in 1911 and entered the service May 15, 1914

Colonel Aubrey K Brown

The Legion of Merit was recently awarded to Col Aubrey K Brown, M C U S Army, of Fort Moultrie South Carolina As stated in the citation, he displayed outstanding professional and administrative ability as commanding officer Regional Hospital, Camp Swift, Texas, from March 1942 to November 1945 The reconditioning program for return to duty or civil status of convalescent soldiers and the program of training for medical units for oversea service organized and supervised by Colonel Brown, were particularly valuable and reflected his keen devotion to the welfare of the sick and wounded Dr Brown graduated from Bennett College of Eclectic Medicine and Surgery, Chicago, in 1912 and entered the service July 1, 1920

Major Andrew J Brislen

The Army Commendation Ribbon was recently awarded to Major Andrew J Brislen, M C , A U S , of Chicago the authorization stating in part, for your high degree of professional ability displayed in your capacity as chief of the general medical branch of the medical division at the AAF Regional and Convalescent Hospital, Coral Gables, Florida, for the year 1945 Not only did you do a superior job as chief of the general medical branch of the medical service but through your devotion to duty, loyalty, industry and ingenuity you organized and administered the procedure in the hospital for medical discharges for enlisted men You put this system into effect and personally supervised it up to the time after VJ day when the patient load in the convalescent services was reduced to a few hundred Through the use of this system and through your personal efforts in coordination with the personnel office the medical boards and the professional services of this hospital were able to save for the government thousands of needless patient days in the hospital, thereby reducing the noneffective rates of organizations serviced by the hospital" Dr Brislen graduated from the University of Chicago School of Medicine and entered the service Nov 14, 1942

Captain Saul Steinberg

The Army Commendation Ribbon was recently awarded to Capt Saul Steinberg M C A U S , of Norristown, Pa, for meritorious service as venereal disease control officer, Camp Carson Colorado, from 1942 to 1944 With an average military strength of 15,000 to 20,000 men at Camp Carson his efforts, which necessitated working many off duty hours, resulted in a very low venereal disease rate at that camp The citation adds that he displayed exceptional ability and outstanding judgment and industry in the coordination and operation of the venereal disease program, in the establishment and effecting of highly beneficial programs and procedures, and in enthusiastic, tireless devotion to the best interests of personnel and patients Dr Steinberg graduated from Jefferson Medical College of Philadelphia and entered the service May 7, 1943 eran is not financially able to pay for private medical care If the Veterans Administration medical service is to apply to all veterans for any disabilities, General Hawley said that the agency's medical department will have to be revised and greater use will have to be made of private hospitals He explained that such a medical program could "never succeed under a full time medical service in government hospitals—it can only be kept at a proper standard through the use of the best private hospitals in the country" Veterans Administrator Omar N Bradley has ordered a radical change in long standing policy to provide more hospital beds for veterans Henceforth non service connected patients with diseases or disabilities requiring medical treatment rather than hospital care will be placed 'on leave' from the hospital and thereafter given what amounts to outpatient care Savings in the patients' time and hospital bed space is expected to be considerable, under the new policy, in cases of heart conditions, arthritis, cancer, diabetes, skin infections and dental care

Treatment of Leprosy

The Advisory Committee on Leprosy in the United States met at the U S Public Health Service Building here in an all-day session and heard reports on current methods of treatment and control of leprosy or Hansen's disease Officials reported that a sulfonamide drug, Promin (sodium p p'diaminodiphenylsulfone N N'-didextrose sulfonate) has been used successfully at the National Leprosarium at Carville, La, in arresting the disease Thirty-eight per cent of 137 patients treated with the drug during two years showed a reversal from positive to negative in bacteriologic tests Other sulfonamide drugs Promizole (4 2'-diaminophyl 5'-thiazolylsulfone) and diasone (disodium formaldehyde sulfoxylate diaminodiphenylsulfone) are said to have shown promise Dr Thomas Parran Surgeon General of the service, revealed that the disease occurs mainly in the Gulf Coast states and is "a public health problem of continuing importance

One Hundred and Twenty-Five Army Medical Officers to Be Released to U. S. Public Health Service

The War Department has announced that one hundred and twenty five Army medical officers who are not classified as specialists may apply to serve their active duty as members of the U S Public Health Service The action was taken to assist the public health service through a difficult period' it was explained Regular Army officers those listed as specialists and physicians who have volunteered to serve as long as twenty four months are excluded from the transfer The department also reminded wartime officers who have returned to civilian life that December 31 is the closing date for applications for Regular Army commissions

Commentators Fear Production of Motion Pictures Glamorizing Use of Drugs

Fears that relaxation of the code of the Bureau of Narcotics to permit the making of films depicting drug addiction would result in a cycle of movies with drug traffic plots were expressed by the Catholic National Legion of Decency and others here The code was amended to read 'Illegal drug traffic must not be portrayed in such a way as to stimulate either curiosity or interest concerning the use of or traffic in such drugs, nor shall scenes be approved which show the use of illegal drugs or their effects in detail The Legion of Decency stated that this provision in effect opens the door for the production" of drugs films and "reports indicate that several companies are planning dope' production"

NAVY

EXAMINATIONS FOR MEDICAL CORPS OFFICERS

The Bureau of Medicine and Surgery announces that examinations for the selection of candidates for appointment to the Navy Medical Corps will be held on Feb. 3-7, 1947, when boards of examiners will conduct physical and professional examinations for eligible candidates at twenty naval hospitals throughout the country. Those selected may be appointed to the grades of Assistant Surgeon or Acting Assistant Surgeon with the rank of Lieutenant (junior grade). Candidates must be citizens of the United States, between the ages of 21 and 32 (upper age level 31 for Acting Assistant Surgeons), must be graduates of approved medical schools and meet the physical requirements for appointment. Graduates of approved medical schools in the United States or Canada who have completed internship in accredited hospitals are eligible to take the examination for Assistant Surgeon. Those selected, following confirmation by the Senate, will be appointed and receive orders assigning them to a naval medical facility for active duty.

All students enrolled in approved medical schools who will have completed the third year of their medical course prior to date of the examinations are eligible to take the examinations for Acting Assistant Surgeon. On receipt by the Navy Department of certification that the candidate has satisfactorily completed his medical education, those selected will be appointed Acting Assistant Surgeons and issued active duty orders to naval hospitals for intern training.

Detailed information as to form and procedure of application may be obtained from the Offices of Naval Officer Procurement or from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

LECTURE BY DR. CRILE

Dr. George Crile Jr. of Cleveland, Ohio, was the guest lecturer, December 12, at the National Naval Medical Center, Bethesda, Md. This is the third in a series of lectures sponsored by the Naval Medical School. Rear Admiral Clifford A. Swanson, Surgeon General of the Navy, introduced Dr. Crile, who discussed "Nutrition, Fluid and Electrolyte Balance for the Postoperative Patient."

NAVY AWARDS AND COMMENDATIONS

Lieutenant Andrew F. LoPinto

The Navy Commendation Ribbon was recently awarded to Lieut. Andrew F. LoPinto (MC), U.S.N., of South San Francisco, Calif., "for excellent service in the line of his profession and duty as junior medical officer aboard the U. S. S. *Ormsby* (APA-49) from Feb. 1, 1944 to Nov. 15, 1944 during the amphibious assaults and capture of Kwajalein, Aitope, Guam, Pelelien and Leyte." The citation mentions Lieutenant LoPinto's consistent display of "exceptional leadership in the organization of the medical department personnel and the highest professional skill in meeting unique problems in surgery. His devotion to duty during the assault on Guam, when he attended to the wounded continuously for seventy-two hours without rest or sleep, saved many valuable lives. His conduct and accomplishments under hazardous combat conditions were in keeping with the highest traditions of the United States Naval Service." Dr. LoPinto graduated from the University of Southern California Medical School in 1942 and entered the service in August of that year.

MISCELLANEOUS

SPECIALISTS WANTED FOR GOVERNMENT POSITIONS

The U. S. Civil Service Commission has announced an examination to fill high grade positions in various medical fields. These positions are located in Washington, D. C., and vicinity. The positions are Specialist in Epidemiology (War Department), Specialist in Pathology and Specialist in Bacteriology (Army Institute of Pathology), Specialist in Medical Pharmacology (Food and Drug Administration), Specialist in Maternal and Child Health (United States Children's Bureau) and Health Director (various agencies). The salaries range from $7,102 to $9,975 a year. Written examination is not required. A preliminary review will be made of the training and experience of each applicant, and those who do not meet the requirements will be so notified. Final ratings for the positions at the appropriate salary grade will be made based on a scale of 100. Veteran preference based on honorable separation from the armed forces are given under certain conditions in competitive examination for original appointment. Five points are added to the earned rates of the applicant for his or her active service in the armed forces during any war. Ten points are added to the earned ratings of applicants who establish a claim to preference as: (a) a disabled veteran; (b) the wife of a disabled veteran who is disqualified for appointment because of his service connected disability, and (c) the unmarried widow of a deceased ex-service man who served in the armed forces on active duty during any war.

Applicants must be graduates of an approved medical school, but graduates of schools "unapproved" by the American Medical Association will be accepted provided they are qualified in all other respects and have supplemented their education with at least one year in the military service or the U. S. Public Health Service with unrestricted duties as commissioned medical officers, such duties including the treatment of patients. Applicants must also have had progressively responsible experience or education in a specialized medical field and for some positions must also be currently licensed to practice medicine and surgery. The maximum age limit, 62 years, will be waived for persons entitled to veteran preference.

Applicants must also be citizens of or owe allegiance to the United States, or must be citizens of the Republic of the Philippines. A physical examination will be made by a federal medical officer. Appointments will be made subject to investigation and will be probational unless otherwise limited. Probational appointments become permanent after a satisfactory probational period of one year.

Interested persons may secure application forms from post offices, from the United States Civil Service Commission in Washington, D. C., or from the Civil Service regional offices.

MARY E. SWITZER AWARDED CERTIFICATE OF MERIT

The President recently awarded the Certificate of Merit to Miss Mary Elizabeth Switzer of Washington, D. C. The citation read as follows: "While serving in her regular capacity as Assistant to the Administrator, Federal Security Agency, she was Assistant to the Chairman, Procurement and Assignment Service for Physicians, Dentists, Veterinarians, Sanitary Engineers and Nurses, War Manpower Commission, and to the Director, War Research Service, Federal Security Agency. As special adviser and counselor to each during a period when the successful prosecution of the war required unusual intelligence, foresight and integrity in certain medical and scientific enterprises, Mary E. Switzer rendered invaluable aid in the organization and coordination of these activities throughout the United States which was far beyond what would be required and expected. In this work much of which was of the highest secret classification, her exceptional knowledge of government administration and of leaders in administrative positions and in medicine and science, both within and without the government service, combined with her high intelligence, indefatigable effort, and the confidence and trust which she inspired on the part of all concerned, contributed in large measure to the success of two war projects of indispensable value to the country in the prosecution of the war."

CALIFORNIA

Refresher Courses on Cancer—The first of a series of refresher courses on cancer for general practitioners in California will be given at Los Angeles County General Hospital January 6 8 They are being offered by the California Cancer Commission and the California Division of the American Cancer Society and will be under the supervision of the Tumor Board of the Los Angeles County General Hospital The course will include both day and evening clinics Applications should be sent to Dr E M Butt, 1200 North State Street, Los Angeles 33

Howard West Takes New Position—Dr Howard F West, Los Angeles, was appointed to the newly created position of medical director of the Los Angeles County Department of Charities, effective Nov. 1, 1946 Newspapers report that Dr West will serve as medical adviser to County Superintendent of Charities Arthur J Will and the medical directors of the various hospitals and will 'carry on scientific and professional activities relating to medical policies, problems and programs of the county" Dr West is president of the American Heart Association and clinical professor of medicine at the University of Southern California

Annual Clinical Assembly in Obstetrics and Gynecology.—The second Annual Mid-Winter Clinical Assembly in Obstetrics and Gynecology will be held in Los Angeles February 10 to 15 The faculty will include Dr Albert H Aldridge, chief surgeon, Woman s Hospital, New York, Dr Joseph L Baer of the University of Illinois College of Medicine, Chicago, Dr Frieda Fromm-Reichmann of Chestnut Lodge Sanitarium, Rockville, Md , Dr George Van S Smith of Harvard Medical School, Olive Watkins Smith, Ph D , of the Fearing Research Laboratory in Massachusetts and William F Windle, Ph D , of the recently established University of Washington School of Medicine in Seattle Obstetricians and gynecologists from all the Western states are invited to attend Dr Roy Fallas, Los Angeles 5 is the secretary treasurer

ILLINOIS

Personal—Dr Dan Morse Columbus Ohio, has been appointed medical director and superintendent of the Peoria Municipal Tuberculosis Sanitarium succeeding Dr Maxim Pollak, recently resigned

Basic Science Course—Registration for the second nine month basic science course in the University of Illinois College of Medicine opened January 1 This is another in a series of professional postgraduate courses designed primarily to meet the needs of medical officers returned from service in the armed forces

Chicago

Meeting of Internists—The Chicago Society of Internal Medicine will meet January 27 at the Drake Hotel. The program is as follows: Drs. Ralph E Dolkart and Robert N Hedges, "Present Incidence of Amebic Dysentery in the Chicago Area', Drs S Ernest G McEwen and Richard H Young, Evanston, "Bacillary Dysentery as the Etiology of Reiter's Syndrome', Drs Howard W Crail, Howard L Alt Evanston and Walter H Nadler, "Myelofibrosis Associated with Tuberculosis"

Cook County Health Survey—A Chicago-Cook County health survey, conducted recently by the U S Public Health Service, made four recommendations to the city and county in their battle against venereal disease (1) that routine blood examinations for syphilis be instituted in all tax-supported hospitals and clinics and encouraged in voluntary hospitals and clinics, (2) that a large venereal disease clinic be organized in Cook County Hospital and the county health department be provided with a full time venereal disease officer, (3) that the intensive treatment center, 2449 Dearborn Street, be moved to the new west side medical center and that clinics be located in association with general health clinics or hospitals and (4) that the public health service be released immediately from administering the city program and that a city health department employee be named director

MASSACHUSETTS

License Restored.—The Board of Registration of Medicine on November 22 voted to restore the certificate of registration of Dr Theodore Rosen, formerly of Boston

Rehabilitation Program—Dr Augustus Thorndike, Associate in Surgery, Harvard Medical School, and recently head of the rehabilitation division in the Surgeon General's Office, U S Army, addressed the New England Society of Physical Medicine in Boston, Dec 18, 1946 on The Army Patient Rehabilitation Program of World War II ' Dr Thorndike also showed a motion picture of the rehabilitation program produced recently in Hollywood under the direction of the Army

MINNESOTA

Swedish Radiologist Addresses County Society—Dr Nils Westermark Swedish radiologist, was the speaker at the Hennepin County Medical Society, Minneapolis December 9 on the subject "Bronchogenic Carcinoma ' Dr. Westermark is a Docent in radiology at the Caroline Institute, University of Stockholm and radiologist at St Goran s Hospital

NEW JERSEY

Society of Surgeons of New Jersey—An entire day was given over to the Annual Meeting of the Society of Surgeons of New Jersey, Nov 20, 1946 in Newark, the morning being devoted to operations at the City Hospital and the afternoon to the presentation of papers, a motion picture on reconstructive surgery of the lower extremity, and a tour of the Pathological Laboratory and Museum Dr Herbert W Nafey, New Brunswick, was elected president for the ensuing year Twenty-three new active members were elected at this meeting

NEW YORK

Lecture on Function of Adrenal Cortex—Dr Cyril N H Long, Sterling professor of Physiological Chemistry at Yale University, will speak at the New York Diabetes Association at an open meeting, January 11, 8 30 p m , at Blumenthal Auditorium Mount Sinai Hospital, New York His subject will be "Recent Studies on the Function of the Adrenal Cortex

Fellowship in Rheumatic Disorders—Dr Norman Spitzer, Yonkers, was appointed Robert Trubek fellow in rheumatic disorders for 1946 1947 according to Dr Currier McEwen, dean, New York University College of Medicine The fellowship open to physicians with at least two years of previous training in internal medicine carries a stipend of $2 500 and provides a year of research and special clinical training at the University and Bellevue Hospital

Clinic Day at Niagara Falls—The Academy of Medicine, Niagara Falls has arranged a special program of guest speakers for clinic day which will be held at Niagara Hotel on March 8 Dr Walter F Kvale, Mayo Clinic, Rochester, Minn , will speak on Prevention of Venous Thrombosis and Pulmonary Embolism' Dr John Romano, professor of psychiatry, University of Rochester School of Medicine, on "The Diagnosis of Neurosis , Dr Gabriel Tucker, Graduate Medical School of the University of Pennsylvania, on 'Obstructive Dyspnea," and Dr Newlin F Paxson professor of clinical obstetrics, Hahnemann Medical College, Philadelphia, on "Extraperitoneal Cesarean Section At the dinner meeting Dr Morris Fishbein, Chicago, Editor of THE JOURNAL, will speak on 'The Rise and Fall of Charlatanism' The chairman of the program committee is Dr Vincent D Leone, and the president of the academy is Dr Joseph V Farugia

Richmond County Postgraduate Lectures—Postgraduate lectures for the Richmond County Medical Society have been arranged by a committee on public health and education of the Medical Society of the State of New York Lectures will be given Thursday afternoons at 3 30 in the auditorium of the U S Marine Hospital, Stapleton Staten Island On January 2 Dr Homer F Swift, Hospital of the Rockefeller Institute for Medical Research, spoke on "Rheumatic Fever—Rheumatic Heart Disease", January 9 Dr Hugh Chaplin, clinical professor of pediatrics, New York University College of Medicine, will speak on "Care and Feeding of Prematures", January 16 Dr Nathan Sobel, assistant clinical professor of dermatology and syphilology, New York Post-Graduate Medical School, Columbia University 'Diagnosis and Treatment of Common Skin Diseases , January 23 Dr Lloyd F Craver, assistant professor of clinical medicine, Cornell University Medical College, 'Treatment of Lymphomatous Diseases,' and January 30 Dr Herman O Mosenthal, professor of clinical medicine, New York Post Graduate Medical School, Columbia University, 'Insulin in the Treatment of Diabetes"

New York City

Cooperative Investigation of Food Poisoning—In an effort to discover the cause of a recent outbreak of 20 cases of mild food poisoning among New Yorkers who ate Norwegian sardines packed in aluminum cans the New York State Health Department and the Norwegian government are conducting a cooperative investigation Jerome Trichter, director and Edwin W C Ludewig assistant director of the health department's bureau of food and drugs have sailed for Norway Two Norwegian scientists have arrived to study the situation here The city health department immediately placed an embargo on all Norwegian sardines packed in aluminum cans and the Norwegian government has held up the export of this product

Award Scholarships for Study of Eye Diseases—The recipients of four scholarships for advanced study of eye diseases at New York University College of Medicine were announced November 27 The physicians selected by the University's department of ophthalmology for the $500 awards are Dr Edward Danforth, Bainbridge, N Y, Dr Charles P Goldsmith, Catasauqua Pa Dr Jonathan L Harris, Elberon N J, and Dr Hugh E McGhee Jeffersonville N Y All are postgraduate students at the College of Medicine, and are specializing in ophthalmology The Eye Conservation Fund, Inc, of the New York Lions Club initiated the scholarship plan last spring with a gift of $2 000 to the college Mr Ernest R Fryxell, chairman of the Eye Conservation Fund, stated that the Lions Club will provide four scholarships annually for advanced study of eye diseases at New York University

Campaign to Raise $2,000,000 for Institute of Rehabilitation—The committee for the Institute of Rehabilitation of the New York University-Bellevue Medical Center is conducting a campaign to raise $2,000,000 for the new Institute of Rehabilitation Cochairmen of the committee are Major Gen William J Donovan, former director of the Office of Strategic Services, and Mrs Bernard F Gimbel, a former member of the Board of Directors of the Beth Israel Hospital The institute will teach and train, in the broad field of rehabilitation physicians medical students, physical therapists, occupational therapists, physical rehabilitation specialists, social workers, administrators and teachers, and will also provide for the actual care of patients as well as for research in this field It is proposed that the institute provide care for 300 patients, about 100 in dormitory facilities and 100 in the outpatient department, including physical rehabilitation, educational and vocational guidance and psychosocial adjustments for persons with all types of handicaps These plans, however, will not duplicate the programs of existing agencies in this field The executive vice chairman of the committee and chairman of the new department of rehabilitation and physical medicine of the New York University College of Medicine is Dr Howard A Rusk

NORTH CAROLINA

Annual Symposium at Durham—A medical and surgical symposium sponsored by the Watts Hospital staff will be held February 12 and 13 at Durham Meetings begin at 11 a m The program is as follows

Dr Sidney Farber and Dr Charles D May of Boston, Clinicopathologic Conference
Dr Leland S McKittrick, Boston "Surgical Aspects of Diabetes"
Dr Howard F Root, Boston "Recent Advances in the Study and Treatment of Diabetes '
Dr Joseph Stokes Jr Philadelphia "Viral Hepatitis"
Dr Francis C Wood, Philadelphia, "Pericardial Scars '
Col J E Ash and Dr Wallace M Yater of the District of Columbia Clinicopathologic Conference
Dr Albert M Snell Rochester, Minn, 'Clinical and Physiologic Aspects of Portal Cirrhosis
Dr Monroe J Romansky, District of Columbia, 'The Current Status of Calcium Penicillin in Beeswax and Peanut Oil
Dr Charles A Doan, Columbus, Ohio 'Present Status of Effective Specific Therapy Based on Exact Hematologic Diagnosis'

OHIO

Program of Cincinnati Academy.—The scientific program for the entire year of the Academy of Medicine of Cincinnati has already been prepared At the January 21 meeting Dr Edgar Allen, associate professor of medicine, Rochester, Minn will discuss "The Present Status of Anticoagulant Therapy," and on February 4 Dr Herbert F Traut, professor of obstetrics and gynecology, University of California Medical School, San Francisco, "The Present Status of Hormone Therapy in Gynecology" The Rachford lectures will be delivered February 18 and 19 by Dr Alfred Blalock, professor of surgery, and Dr Helen B Taussig, associate professor of pediatrics, Johns Hopkins University School of Medicine, Baltimore for "Diagnosis, Surgical Treatment and Results in Congenital Heart Disease '

PENNSYLVANIA

Annual Meeting of Psychiatrists—At the eighth annual dinner meeting of the Pennsylvania Psychiatric Society in Philadelphia recently former U S Supreme Court Justice Owen J Roberts spoke on 'What the Layman Can Do About Mental Illness' Dr Charles H Henninger, Pittsburgh was elected president of the society, Dr LeRoy M A Maeder of Philadelphia, president-elect and Dr Philip Q Roche, Philadelphia secretary-treasurer

Fellowship in Diabetic Research Established—A new fellowship in clinical diabetic research has been established at the hospital of the University of Pennsylvania, it was announced today by Dr George W McClelland president of the University The fellowship was made possible through the generosity of Philadelphia and Wilmington friends of the university In its first year the fellowship will be concerned chiefly with the development of new technics to improve the care of the diabetic patient and new methods of controlling the disease Although the fellowship will represent a separate research activity, it will work in cooperation with the George S Cox Medical Research Institute

Philadelphia

Postgraduate Seminar in Radiology—The second annual Philadelphia postgraduate seminar in radiology will be held March 30 to April 4 as announced by Dr Burton R Young, chairman of the special committee of the Philadelphia Roentgen Ray Society Dr Paul C Swenson has been appointed director of lecture sessions Dr Calvin L Stewart is secretary The course will be limited to one hundred radiologists The tuition fee will be $50

Personal—Dr Clarence N Smith, an officer of the regular Navy since 1918, has been appointed industrial medical consultant for the eastern area of Pennsylvania for the bureau of industrial hygiene, Pennsylvania Department of Health——Dr B S Oppenheimer, professor of clinical medicine, Columbia University College of Physicians and Surgeons and chief of medicine, Mount Sinai Hospital, New York, gave an address on neurocirculatory asthenia at a meeting December 12 at the Wolffe Clinic, Philadelphia

TENNESSEE

Physician Honored.—A public celebration was held in Calhoun in honor of Dr Henry F Taylor on his sixty-sixth birthday Dr Taylor has practiced in the town for forty years

Ernest Goodpasture Wins Award—Dr Ernest W Goodpasture, professor of pathology and dean of the Vanderbilt University School of Medicine, Nashville, was presented with the tenth annual Kappa Sigma Fraternity "Man of the Year" cup on December 7 Dr Goodpasture was a Kappa Sigma at Vanderbilt University, where he received his B. A. degree in 1907. Earlier this year he received the $5,000 Passano Foundation award for his work in medical research (The Journal, April 27, 1946, page 1256).

VIRGINIA

Advisory Board on Mental Hygiene.—Four appointments were recently announced to the governor's advisory board on mental hygiene. The recipients are Dr. Patrick H. Drewry Jr., Medical College of Virginia, and Drs. Claude L. Neale, George S. Fultz Jr. and Harry Brick, all of Richmond.

Seaboard Medical Society.—Dr. Oscar R. Yates, Suffolk, was elected president of the Seaboard Medical Society December 5 at a three day meeting of physicians from Virginia and North Carolina. Other officers elected are Dr. Dewey H. Bridger, Bladenboro, first vice president; Dr. Walter P. Adams, Norfolk, second vice president; Dr. Charles H. Lupton, Norfolk, third vice president, and Dr. Clarence Porter Jones Sr., Newport News, secretary-treasurer.

Personal.—Dr. Granville L. Jones, Marlboro, N. J., has been appointed superintendent of the Eastern State Hospital, Williamsburg, succeeding Dr. Joseph E. Barrett, Marian, who is now state commissioner of mental hygiene and hospitals.——Dr. David L. Harrell Jr. has been appointed in charge of the Lynchburg state colony, Richmond. His position as superintendent of the Western State Hospital, Staunton, has been filled by Dr. James B. Pettis, Norfolk.——Dr. Marion S. Fitchett, Norfolk, has been appointed a member of the Virginia state board of medical examiners to succeed Dr. Philip St. L. Moncure, Norfolk.

WEST VIRGINIA

Mental Hygiene Clinic.—The first mental hygiene clinic of its kind ever established in West Virginia has been opened by the Veterans Administration at its regional office in Huntington. Dr. Edward F. Reaser, former assistant superintendent of the Huntington State Hospital, has been named supervisor and chief psychiatrist at the clinic. He resigned as assistant at the Huntington State Hospital effective November 15. Service connected nervous disorders will be treated at the clinic through a process of study and reeducation. Members of the staff will be graduate physicians in this specialized branch of medicine, psychologists and social service workers.

Central Society Meeting.—Dr. J. N. Reever of Charleston was the guest speaker at the quarterly meeting of the Central West Virginia Medical Society held at Gassaway December 5. He gave an illustrative talk on the "Surgical Treatment of Tuberculosis." A round table discussion followed. The following physicians were elected honorary lifetime members of the society: Drs. O. O. Eakle and H. S. Brown, Sutton; Dr. L. W. Deeds, Buckhannon; Drs. G. M. Burton and S. H. Burton, Weston; Dr. J. B. Dodrill, Webster Springs; Dr. H. O. Van Tromp, French Creek, and Dr. Charles B. Rohr, Alum Bridge. Dr. Ralph M. Fisher of Weston and Dr. B. L. Page of Buckhannon were elected members of a committee to arrange for the organization of an auxiliary to the Central Vest Virginia Medical Society.

WISCONSIN

Inaugurate Surgical Society.—The inaugural meeting of the Wisconsin Surgical Society was held in Milwaukee November 15. Dr. F. Gregory Connell, Oshkosh, gave the "President's Address." Dr. Frederick A. Coller, professor of surgery, University of Michigan Medical School, spoke on "Abdominal Incisions and Early Ambulation." There were operative clinics at the Milwaukee, Columbia, Veterans Administration and Milwaukee County Hospitals, and dry clinics in the amphitheater at the Milwaukee Children's Hospital. This new group was organized September 14 at a meeting in Milwaukee with fifty founder members (The Journal, Oct 11, 1946, page 401).

Brief Course in Cardiology.—A series of five day intensive courses for Wisconsin physicians are to be given at the medical school and Wisconsin General Hospital in Madison. The first course will be Jan. 13 to 17, 1947, on cardiology. The work will be of a practical nature intended to present to general practitioners the current diagnostic and therapeutic measures available. It will be under the supervision of Drs. C. M. Kurtz and H. H. Shapiro. The fee will be $25 for the five day course. Further information can be had from Dr. Llewellyn R. Cole, coordinator of graduate medical education, Wisconsin University Medical School.

PUERTO RICO

Organize Women's Medical Chapter.—Thirty-one women members of the Medical Association of Puerto Rico have organized the Women's Chapter of the Puerto Rico Medical Association under the chairmanship of Dr. Dolores M. Pinero, an official of the Insular Department of Health.

New Health Commissioner.—The governor has designated Dr. Juan A. Pons, San Juan, as head of the Department of Health of Puerto Rico to succeed Dr. Antonio Fernos Isern, who was recently named resident commissioner of Puerto Rico in the United States. Dr. Pons, who was educated in American universities, was until recently director of municipal hospitals for the city of San Juan.

Large Increase in Premedical Students.—An increase of 179.2 per cent in the registration of premedical students alone over that of 1945 at the University of Puerto Rico, an increase of 69.3 per cent in pharmacy students and of 46.8 per cent in liberal arts students, due in part to the large number of veterans who have returned to the island, caused the Puerto Rico Pnanning Board to submit a six year expansion program involving an expenditure of nearly $15,500,000. Large numbers of premedical students are going to Mexico, Cuba and other Latin American countries because of the overcrowded situation in their own country and in the United States.

GENERAL

Fellowship Open to Women Physicians.—The Women's Medical Association is offering a Mary Putman Jacobi Fellowship for medical research. This fellowship of $1,000 will be available in October and is open to every woman physician, either American or foreign, who is a graduate of a reputable medical school. Application blanks may be obtained from the secretary of the committee, Dr. Phebe L. DuBois, 150 East Seventy-Third Street, New York 21.

Hospital Association Midyear Conference.—The midyear conference of presidents and secretaries of the American Hospital Association will be held February 7 and 8 at the Drake Hotel, Chicago. Its purpose is to assist the officers of state hospital associations in coordinating and developing their programs to improve and raise standards of hospital care. Dr. Vane M. Hoge, Washington, D. C., will discuss the administration of the hospital service and construction act.

Recommends Counter Antivivisection Legislation.—Dr. A. J. Carlson, Chicago, president of the National Society of Medical Research, advocates that medical scientists take the initiative on counter antivivisection bills with legislation of their own to guide the legislatures in their consideration of animal experimentation. It is expected from current newspaper reports that antivivisection legislation will be introduced in forthcoming state legislature sessions. The National Society of Medical Research, which was organized early this year under sponsorship of the Association of American Medical Colleges, is taking the lead in counter antivivisection legislation programs. Members and endorsers of the society include the Chamber of Commerce of the United States, the American National Red Cross and many scientific groups. Officers of the society are at 25 East Washington Street, Chicago.

New Public Health Association Officers.—At the annual meeting of the American Public Health Association in Cleveland, November 12 to 14, the following officers were elected: Harry S. Mustard, dean of the School of Public Health, Columbia University, president; Martha M. Eliot, associate chief, Children's Bureau, U. S. Federal Security Agency, president-elect; Gregoire F. Amyot, provincial health officer, Provincial Board of Health, Victoria, British Columbia, Canada, vice president; A. Fernos Isern, recently commissioner of health, Puerto Rico, vice president; H. A. Whittaker, director, Division of Sanitary Engineering, Minnesota School of Public Health, vice president, and Louis I. Dublin, vice president and statistician, Metropolitan Life Insurance Company, treasurer.

Award for Research in Nutrition.—The American Institute of Nutrition will present an award at its annual meeting in Chicago, May 18 to 22, in recognition of research which has emphasized the significance of the components of milk or dairy products. As this is the Borden award, employees of the Borden Company are not eligible for this honor. While the award will be made primarily for the publication of specific papers, the judges may recommend that it be given for important contributions over an extended period of time. Nominations must be in the hands of the chairman of the Nominating Committee, Genevieve Stearns, State University of Iowa College of Medicine, Iowa City, by January 15 and should be accompanied by data relative to the nominee and his research.

Atomic Energy Medical Forum.—At a meeting of the American Pharmaceutical Manufacturers' Association at the Waldorf Astoria, New York, Dec. 10, 1946, Dr. Shields Warren, assistant professor of pathology at Harvard Medical School, Boston, read a paper on "Physiological Reactions to Radioactive Isotopes"; Dr. Frank H. Krusen, Mayo Clinic, Rochester, Minn., "General Medical Aspects of Atomic Energy"; Samuel K. Allison, Ph.D., director of the Institute of Nuclear Studies, University of Chicago, "Atomic Energy in the Physical Sciences"; Paul C. Aebersold, Ph.D., Research Division, Manhattan District, Oak Ridge, Tenn.; "Use of Radioactive Isotopes by the Pharmaceutical Profession," and Dr. G. Failla, Columbia University College of Physicians and Surgeons, "Nuclear Physics and Medical Research."

New National Formulary Published.—The Council of the American Pharmaceutical Association has completely revised and enlarged the National Formulary, which was to be available in December 1946. The publication provides official specifications for many widely used drugs not previously included in either the U. S. Pharmacopeia or the National Formulary. The eighth edition represents the culmination of four years of planning and work by members of the committee on the National Formulary, the staff of the American Pharmaceutical Association laboratory and hundreds of collaborators connected with collegiate, institutional, governmental and industrial laboratories. Dr. Justin L. Powers is chairman of the committee of revision. It will be necessary for practicing pharmacists and others to have the book on hand prior to April 1, 1947 to meet the various state pharmacy and food and drug acts. Copies may be secured from the Mack Publishing Company, Twentieth and Northampton streets, Easton, Pa.

Association of Electroencephalographers.—The fifth meeting of the Eastern Association of Electroencephalographers was held at the Massachusetts General Hospital, Boston, December 4 and 5. The program included the following speakers:

W. Grey Walter, M.A., Burden Neurological Institute, England, Status of Electroencephalography in Europe and Remarks on International Meetings and Electroencephalographic Societies.

Dr. Frederick A. Gibbs, Chicago, The Problem of Frequency Analysis of the Electroencephalogram.

Dr. George Engel, Rochester, N. Y., Experiences with Manual Analysis of the Electroencephalogram.

Dr. Robert Cohn, Washington, D. C., Experiences with Automatic Phase Analysis.

At a joint meeting of the association with the Boston Society of Neurology and Psychiatry the speakers were Robert S. Schwab, "Application and Limitations of Electroencephalography in a General Hospital"; Hudson Hoagland, Sc.D., "Brain Wave Frequencies and Brain Chemistry," and W. Grey Walter, "Clinical Application of Automatic Analysis of the Electroencephalogram and Demonstration."

Prizes for Scientific Studies of Sugar.—Dr. Harlow Shapley, chairman, National Science Fund, National Academy of Sciences, Washington, D. C., announces that scientists of all countries have been invited to compete for prizes totaling $40,000 posted by the Sugar Research Foundation in order to stimulate scientific studies of sugar as a food and an industrial raw material. Members of the advisory committee in charge of recommendations for the awards are William C. Stadie, professor of research medicine, University of Pennsylvania; A. Baird Hastings, professor of biochemistry, Harvard University; Charles F. Kettering, General Motors Corporation; Carl S. Marvel, professor of organic chemistry, University of Illinois; Edmund W. Sinott, professor of botany, Yale University, and Vincent Du Vigneaud, professor of biochemistry, Cornell University Medical College. Awards of $5,000 will be given in 1947, 1948 and 1949 with a grand prize of $25,000 in 1950 for the most significant discovery of the preceding five years. Winners of the preliminary awards are also eligible for the grand prize. Entries for the award, which will be given on or about March 15, should be in the hands of the executive secretary, National Science Fund, National Academy of Sciences, Washington, D. C., not later than February 1.

Indictment Charging Restraint of Trade in Surgical Dressings.—Attorney General Tom Clark announced that a federal grand jury at Boston November 21 returned an indictment charging four corporations and five individuals with conspiracy to restrain domestic and foreign trade and commerce in the manufacture, sale and distribution of surgical dressings in violation of the Sherman Antitrust Act. The defendant corporations are Johnson & Johnson, New Brunswick, N. J.; Johnson & Johnson International, New Brunswick, N. J.; Parke, Davis & Co., Detroit, and Kendall Company, Boston. The individuals indicted are E. Briar, Detroit, Parke, Davis & Co. secretary and foreign sales manager; Arthur Clapham, New Brunswick, N. J., Johnson & Johnson director of overseas operations and president of Johnson & Johnson International; Earl E. Dickson, New Brunswick, N. J., Johnson & Johnson vice president in charge of hospital division; L. H. Nichols, Chicago, Kendall Company manager of hospital dressings, and Charles K. Perkins, Chicago, Kendall Company general sales manager. Attorney General Clark said that the indictment charges that the defendant corporations together produce and sell about 75 per cent of the total annual production of surgical dressings in the United States and that they agreed on the prices and terms for the sale of surgical dressings throughout the United States and in foreign commerce. Wendell Berge, Assistant Attorney General in charge of the Antitrust Division, stated: "Municipalities and the federal government are among the largest purchasers of surgical dressings. This case is part of the program of the Antitrust Division to eliminate the price fixing and to break up monopolies in the sale of those items purchased in large quantities by the federal, state and local governments. This case was instituted as a result of complaints made to the Department of Justice by municipalities."

FOREIGN

Anniversary of Rheumatic Council.—The Empire Rheumatism Council celebrated its tenth anniversary in London, October 26 to 29. Mr. Bevan, the Minister of Health, received the delegates. Among those in attendance were Lord Horder, the Minister of Agriculture, and the presidents of the colleges of physicians and surgeons. Dr. Loring Swain of Boston presented the greetings of the Pan American Rheumatism League. Professor J. Axel Höjer, chief medical officer of Sweden, lectured on the organization of research and treatment of rheumatism in that country. A symposium was opened on the application of virus work to polyarthritis in men and animals by Dr. G. M. Dindlay and Prof. C. H. Andrewes. The Heberden Society gave a dinner, and the British Council, a reception to some 200 guests who were welcomed by Sir Edward Mellanby, director of the Medical Research Council.

Trudeau Festival in Japan.—The "Recuperation Festival" known as the "Trudeau Festival," in honor of Edward Livingston Trudeau, was revived and observed throughout Japan, according to the Nippon *Times*, October 5. Celebrations were held at the 149 tuberculosis sanatoriums which are under the supervision of the Nippon Medical Corps. During the festival these sanatoriums were open to the public, and medical treatment was freely dispensed there. The program permits during the three day festival home tuberculous patients to enter sanatoriums under the supervision of the medical corps and stay there for six days free of charge, receiving instructions in their recuperation. The first day is called "Hospital Treatment Day," the second "Recuperation Day" and the third day is devoted to talks, entertainment and hunting treasures. The Nippon *Times* says that the state tuberculosis sanatoriums have about 25,000 beds and the 10,000 private sanatoriums more than 60,000 beds.

Congress of School and University Hygiene.—The Society of Medical Inspectors of the schools in the district of Seine and the French Society of School Hygiene are organizing a Congress of School and University Hygiene to be held in Paris, June 25-29, under the auspices of the ministers of national education and of public health. The organizers of the congress hope that doctors interested in school hygiene in various countries will participate in the congress either as discussers or as reporters. Participation and registration in the congress are free. Collected reports, which will be published a month after the congress, may be subscribed for, the price to be fixed at a later date. Members who desire to receive a copy of a report or who wish to make a communication are asked to apply to the general secretary. On the occasion of this congress the French Society for School Hygiene will propose the creation of an international association to be charged with the organization of periodic congresses and establishment of relations between doctors in different countries who are interested in the problems of school hygiene. Correspondence concerning the congress should be addressed to Dr. Pierre Delthil, Secretary General, 46, Rue de Naples, Paris.

Deaths in Other Countries

Dr. Adolf Liechti, professor of radiology, University of Berne, Switzerland, died August 26, aged 48.——**Vladimir V. Lebedenko**, head of the neurosurgical clinic of the Moscow Medical Institute, Russia, died October 15.——**Lieut. Gen. Nikolai Nilovich Burdenko**, chief surgeon of Russia's armed forces and a deputy of the Supreme Soviet, aged 68.

Deaths

Frank Reid Mount ⊕ Portland, Ore.; born in Springfield, Ore., in 1888; Columbia University College of Physicians and Surgeons, New York, 1912; assistant clinical professor of medicine at the University of Oregon Medical School; member of the House of Delegates of the American Medical Association in 1945; member of the North Pacific Society of Internal Medicine; fellow of the American College of Physicians; served as president of the state board of health; specialist certified by the American Board of Internal Medicine; on the staffs of the Good Samaritan and Multnomah hospitals; served during World War I; began active duty as a lieutenant colonel in the medical corps, Army of the United States, in July 1942, and service terminated in December 1944; died October 11, aged 58, of cerebral embolism and coronary occlusion.

John Howell McLean ⊕ Fort Worth, Texas; born in Mount Pleasant, Texas, on June 11, 1877; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1899; Cornell University Medical College, New York, 1901; fellow of the American College of Surgeons; charter member and past president of the Tarrant County Medical Society; president of the old North Texas Medical Society; served as a member of the state board of medical examiners; formerly professor of gynecology at the Fort Worth School of Medicine; during World War II served on the board of appeals for Selective Service and received a medal for his work; died September 20, aged 69, of acute nephritis.

Matthew Cotton Darnell, Frankfort, Ky.; born in 1874; University of Louisville Medical Department, 1907; member of the American Medical Association; past president of the Franklin County Medical Society; city and county physician; formerly county health officer; served as school trustee and as secretary of the Woodford County Board of Education; recently received a "selective service medal" authorized by Congress for serving without compensation in examining selectees during the national emergency; on the staff of the King's Daughters' Hospital; died November 8, aged 72, of injuries received when he was struck by a truck.

Arthur Wight Benson ⊕ Troy, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1914; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; served as president of the board of visitors and on the staff of the New York State Reconstruction Home in West Haverstraw, as consultant in pediatrics at the Mary McClellan Hospital in Cambridge and as pediatrician to the Leonard and Samaritan hospitals; died in the Presbyterian Hospital in New York, November 20, aged 59, of hypertension and lobar pneumonia.

William Thomas McConnell ⊕ Louisville, Ky.; University of Louisville Medical Department, 1918; associate clinical professor of obstetrics and gynecology at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; formerly chairman of the obstetric section of the Southern Medical Association; on the staffs of the Norton Memorial Infirmary, Kentucky Baptist and Louisville City hospitals; at one time associate editor of the *Kentucky State Medical Journal;* died October 16, aged 61, of heart disease.

John William Pennington ⊕ Phoenix, Ariz.; born in Sigourney, Iowa, March 3, 1903; State University of Iowa College of Medicine, Iowa City, 1929; specialist certified by the American Board of Urology; member of the American Urological Association; past president of the Maricopa County Medical Society; in 1945 vice president of the Arizona State Medical Society; interned at the State University Hospital in Oklahoma City; served a residency at the Henry Ford Hospital in Detroit; on the staffs of St. Joseph's and Good Samaritan hospitals; died October 12, aged 43, of an accidental gunshot wound.

John Albert Wilkens ⊕ St. Marys, Mo.; St. Louis College of Physicians and Surgeons, 1902; St. Louis University School of Medicine, 1905; past president of Ste. Genevieve County Medical Society; registered druggist and president of St. Marys Drug Company; president of the board of education of St. Marys; served on the medical advisory board during World Wars I and II; past president of the Chamber of Commerce; at one time assistant in diseases of children at the National University of Arts and Sciences in St. Louis; died November 3, aged 72, of carcinoma.

Jeremiah Frank Armstrong, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; for many years school physician in the city health department; died November 2, aged 69, of shock and hemorrhage following gunshot wound received from an unknown person in an alleged holdup.

John M. Axelson ⊕ Chicago; Bennett Medical College, Chicago, 1900; Northwestern University Medical School, Chicago, 1904; served during World War I; on the staff of the West Suburban Hospital in Oak Park, Ill.; died in the Swedish Covenant Hospital November 11, aged 74, of cerebral hemorrhage.

James William Bailey ⊕ Kosciusko, Miss.; College of Physicians and Surgeons, Memphis, Tenn., 1911; county health officer; on the staff of the Montfort Jones Memorial Hospital in Kosciusko; died November 4, aged 75, of cerebral hemorrhage.

Blenn Rife Bales, Circleville, Ohio; Starling Medical College, Columbus, 1900; veteran of the Spanish-American War; for many years surgeon for the Norfolk and Western Railroad; died October 25, aged 70, of cerebral hemorrhage.

Edward A. Campbell, Carlisle, Ky.; Southwestern Homeopathic Medical College and Hospital, Louisville, 1897; member of the American Medical Association; died November 6, aged 72, of angina pectoris and cerebral hemorrhage.

Leander Marshall Crosby ⊕ Wakefield, Mass.; Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, Canada, 1901; past president of the Middlesex East District Medical Society; died in New York October 24, aged 70, of heart disease.

Alonzo Gustin Dennett, Lowell, Mass.; Rush Medical College, Chicago, 1883; member of the American Medical Association; served on the staff of St. Joseph's Hospital; died October 11, aged 91, of arteriosclerosis.

Rudolph John Eischeid, Dubuque, Iowa; Chicago College of Medicine and Surgery, 1913; past president and secretary of the Allamakee County Medical Society; served for a time as president of the school board of New Albin; on the staffs of St. Joseph Mercy Hospital and the Finley Hospital; died October 25, aged 63, of cerebral hemorrhage.

Leslie Knapp Fenlon ⊕ Clinton, Iowa; State University of Iowa College of Medicine, Iowa City, 1919; also a graduate in pharmacy; for many years city health officer and medical examiner for the Northwestern Railroad; served as a member of the Student Army Training Corps in Iowa City during World War I; on the courtesy staff of St. Joseph Mercy Hospital and on the staff of the Jane Lamb Memorial Hospital; died October 28, aged 53, of coronary occlusion.

Lewis Frick ⊕ Athens, Wis.; College of Physicians and Surgeons of Chicago, 1897; died in St. Joseph's Hospital, Marshfield, Wis., October 31, aged 76, of partial intestinal obstruction and mediastinal tumor.

Harry Theodore Frost ⊕ Wadena, Minn.; Northwestern University Medical School, Chicago, 1920; on the staff of the Wesley Hospital; died October 22, aged 52, of coronary heart disease.

George Thomas Gale, Newport, Ohio; Jefferson Medical College of Philadelphia, 1874; served as vice president and director of the Pleasants County Bank in St. Marys, W. Va., and was formerly a member of the board of education; died October 9, aged 94, of chronic bronchitis.

William Hyman Goldstein ⊕ Kearny, N. J.; University and Bellevue Hospital Medical College, New York, 1917; fellow of the American College of Surgeons; served during World War I; on the staffs of the West Hudson Hospital in Kearny and the Beth Israel Hospital in Newark, where he died October 5, aged 52, of subarachnoid hemorrhage.

H. Herbert Hammond ⊕ Van Buren, Maine; Chattanooga (Tenn.) Medical College, 1900; served on the staffs of the Presque Island (Me.) General Hospital and the Hotel Dieu Hospital; died October 30, aged 75, of heart disease.

Samuel Clifford Henslee, Dillon, S. C.; Hospital College of Medicine, Louisville, Ky., 1898; died October 29, aged 76, of thrombosis.

Roger Wolcott Hubbard ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1927; formerly secretary of the Irving Park Branch of the Chicago Medical Society; served on the staffs of the Ravenswood and Illinois Masonic hospitals; died in the Augustana Hospital October 14, aged 48, of cerebral thrombosis.

George Baigerie Jobson ⊕ Franklin, Pa.; Harvey Medical College, Chicago, 1900; specialist certified by the American Board of Ophthalmology, American Board of Otolaryngology and the American Board of Plastic Surgery; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; past president of the Venango County Medical Society; served as a member and president of the board of education; affiliated with Oil City Hospital; died October 21, aged 77, of myocarditis.

Helen Jeffery Kelly, Milwaukee; University of Minnesota Medical School, Minneapolis, 1939; interned at Swedish Hospital in Minneapolis; diplomate of the National Board of Medical Examiners; formerly connected with the Kentucky State Board of Health in Louisville; died October 29, aged 43, of accidental barbiturate poisoning.

Arthur Samuel Kitchen ⊕ Escanaba, Mich.; University of Toronto Faculty of Medicine, Toronto, Canada, 1899; fellow of the American College of Surgeons; past president of the Delta County Medical Society; served as a member of the city council; on the staff of St. Francis Hospital; died October 30, aged 71, of coronary occlusion.

Edward Newton Lillard, Madison, Va.; Medical College of Virginia, Richmond, 1901; member of the American Medical Association; died October 9, aged 74, of carcinoma of the throat.

Wilbur Wallace McCleary, Remer, Minn.; Chicago Medical College, 1889; died October 22, aged 79, of coronary occlusion.

Robert Sherwood McGeachy, New Bern, N. C.; Bellevue Hospital Medical College, New York, 1894; member of the American Medical Association; served during World War I; health officer of Craven County since 1939; formerly health officer of other counties; died in St. Luke's Hospital October 9, aged 74, of burns received when a gas water heater exploded in the basement of his home.

Ady Royal McKeown, Letts, Iowa; University of Colorado School of Medicine, Denver, 1911; served during World War I; died in the University Hospital, Iowa City, October 29, aged 63, of gunshot wounds.

Elsie Reed Mitchell, Berkeley, Calif.; Colorado School of Medicine, Boulder, 1897; served with the Red Cross in France during World War I and later served with the Near East Relief; died October 8, aged 74, of coronary thrombosis.

Henry Eugene Mitchell, Birmingham, Ala.; University of Tennessee Medical Department, Nashville, 1893; member of the American Medical Association; died in the Norwood Hospital October 11, aged 79, of bronchopneumonia and fractured right hip incurred in a fall.

Paul Morrison, St. Cloud, Fla.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; served during World War I; at one time affiliated with the U. S. Public Health Service Reserve and the Veterans Administration Facilities in Lakeland and Memphis, Tenn.; died October 27, aged 77, of hypertensive heart disease.

Nathan F. Mossell, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1882; past president of the National Medical Association; founder of the Philadelphia branch of the National Association for the Advancement of Colored People and co-founder of the Philadelphia Academy of Medicine and Allied Sciences; founder and for many years medical director of the Frederick Douglass Memorial Hospital; died October 27, aged 90.

Andrew Jackson Nellans, Bond Hill, Ohio; Bennett Medical College, Chicago, 1896; died October 12, aged 78.

Herman Frederick Ohswaldt, Oconto Falls, Wis.; Bellevue Hospital Medical College, New York, 1879; died October 22, aged 89, of chronic myocarditis.

John M. Patterson, Winterhaven, Fla.; Medical College of Ohio, Cincinnati, 1902; for many years practiced in Lima, Ohio; died recently, aged 69.

George P. Paulman, Cumberland, Md.; Baltimore University School of Medicine, 1902; Baltimore Medical College, 1906; died October 13, aged 68.

William H. Perry, Louisville, Ky.; Illinois Medical College, Chicago, 1908; a member of the original board of directors of the Red Cross Hospital; died in Anchorage, October 13, aged 86, of chronic myocarditis.

John Dodge Peters, Great Barrington, Mass.; Columbia University College of Physicians and Surgeons, New York, 1904; served during World War I; died in the Fairview Hospital October 20, aged 67, of bronchopneumonia.

Pedro Platou, Brooklyn; Long Island College Hospital, Brooklyn, 1920; fellow of the American College of Surgeons; member of the American Medical Association; began active duty as major in the medical corps, Army of the United States, in July 1942; chief surgeon of the 231st Station Hospital in England; promoted to lieutenant colonel and at the time of release from active duty in May 1946 held the rank of colonel; on the staff of the Norwegian Lutheran Deaconesses Hospital, where he died October 19, aged 54, of coronary heart disease.

[illegible] ard, Philadelphia; Jefferson Medical [illegible] 1883; died in October, aged 93.

Earl Van Reed ⊕ La Fayette, Ind.; Medical College of Indiana, Indianapolis, 1905; twice served as county coroner; formerly secretary of the board of health of La Fayette; served during World War I; on the staffs of La Fayette Home and St. Elizabeth hospitals; died October 10, aged 67, of right pulmonary embolus.

Walter A. Rivers, Glenwood, Ga.; Atlanta Medical College, 1894; served as a member of the state board of health; died in a hospital at Dublin September 28, aged 79, of cirrhosis of the liver.

Cunera R. Scheffer, Brookline, Mass.; Northwestern University Woman's Medical School, Chicago, 1894; died recently, aged 78, of bronchopneumonia.

Lewis Shirar, Flora, Ind.; Eclectic Medical Institute, Cincinnati, 1901; died October 7, aged 86, of bronchopneumonia.

Frederick Grant Sigman ⊕ Salisbury, N. C.; University College of Medicine, Richmond, 1909; specialist certified by the American Board of Radiology, member of the Radiological Society of North America, Inc., and the American College of Radiology; honorary member of the Medical Society of the State of North Carolina; on the staff of the Rowan Memorial Hospital; died in the University Hospital, Baltimore, October 21, aged 67.

Milton Hamilton Smith, Trumansburg, N. Y.; United States Medical College, New York, 1881; died September 29, aged 90.

Allen Horatio Thatcher, Chicago; Bennett Medical College, Chicago, 1896; died October 20, aged 79, of coronary thrombosis.

Thomas Gordon Tibby, Oakdale, Ill.; Rush Medical College, Chicago, 1894; cashier of the state bank; died in the Sutherland Hospital, Sparta, October 16, aged 75, of shock and brain concussion received when he fell down the basement steps.

George Thomas Twyman ⊕ Independence, Mo.; Rush Medical College, Chicago, 1915; fellow of the American College of Physicians; served on the Mexican border and in France during World War I; on the staff of the Independence Sanitarium and Hospital where he died October 4, aged 58, of diabetes mellitus and cardiac failure.

Hasseltine Stephens Walker, Brandon, Vt.; Northwestern University Woman's Medical School, Chicago, 1893; died October 23, aged 76.

John William Warner ⊕ Washington, D. C.; University and Bellevue Hospital Medical College, New York, 1909; fellow of the American College of Surgeons and the New York Academy of Medicine; served in France during World War I; formerly on the staff of the Roosevelt Hospital in New York, Doctors, Emergency and Georgetown hospitals; died October 29, aged 63.

Josef Werner, Boston; Julius-Maximilians Universitat Medizinische Fakultat, Würzburg, Bavaria, Germany, 1884; died recently of arteriosclerotic heart disease.

Richard E. Wilkinson, McKenney, Va.; Medical College of Virginia, Richmond, 1897; served on the staffs of the Petersburg (Va.) Hospital and the Stuart Circle Hospital, Richmond, where he died September 29, aged 80, of prostatitis and intestinal ulcer.

Charles B. Williams ⊕ Mineral Wells, Texas; University of Texas School of Medicine, Galveston, 1899; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; past president of the Palo Pinto-Parker Counties Medical Society; at one time councilor of the Thirteenth District of the State Medical Association of Texas; president of the Texas Ophthalmological and Otolaryngological Society; on the staff of the Nazareth Hospital; died September 4, aged 72, of cerebral hemorrhage.

Charles Osborne Wright, Luverne, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1890; member of the American Medical Association; died in October, aged 82.

The Milk Conference

An important "Milk Conference" attended by scientists, doctors, producers, industrialists and consumers took place from Sept. 11 to 28, 1946, under the presidency of Professor Terroine. The minister for public health, the minister for food and representatives of the Academy of Medicine were present. Its aim was to establish an effective policy for milk. The milk production of 1,400 million liters in 1939 has fallen to 900 million in 1945. At the same time the birth rate has increased and is continuing to increase. There is also a lack of condensed milk; France needs 2,300,000 cases, and the French factories produce only 600,000 cases; moreover, the import of American condensed milk (360,000 cases yearly) has stopped. The French milk production is provided by small holdings; among 1,500,000 families of peasants, over 70 per cent have fewer than 4 to 5 cows, there is a lack of labor and also of food for cattle. This dispersion results in a poor quality of milk: of 420 million liters of raw milk sold, only 40,000 liters offer any hygienic guarantee. Among nurslings it results in 10 per cent of the deaths due to gastroenteritis. During the Nazi occupation the fat content of the milk diminished. The conference drew attention to the importance of skimmed milk for adults. The recent studies on the biology of cholin, by Prof. Jeanne Levy, director of the laboratory of the Academy of Medicine for the Control of Remedies and by Ernest Kahane, director of the laboratory of the National Center for Scientific Research, have shown, among other things, that cholin, a substance of first importance for alimentation, is not a constituent of the fat globules but of the plasma of milk. The conference also dealt with the addition of antiseptic chemicals to milk and to its byproducts. Professors Tanon and Martel, members of the Academy of Medicine, have condemned the practice of adding bicarbonate of soda to milk powder and of "Chloropicrine" as preservative for milk. They also disapprove the method of oxygenating by pressure recommended by the Germans. Among other measures to be taken, the conference defined two categories of milk: (1) recognized controlled and cooled milk and (2) ordinary milk. At a conference at the academy of medicine, Professor Lesne mentioned that only 70,000 liters of pasteurized milk are distributed daily in Paris. On account of the difficulty in obtaining clean milk from the producers, the bad hygienic condition of containers and the unsatisfactory means of transport, he proposes to create two categories of "pasteurized" milk: Grade A, containing fewer than 30,000 germs per cubic centimeter, and grade B, in which the number of germs does not exceed 100,000 per cubic centimeter.

Pulmonary Embolism

At the forty-ninth congress of the French Association of Surgery, held from October 7 to 12, Fontaine of Strasbourg and Redon of Paris reported the use of ephedrine, atropine and sodium bicarbonate in combination as a preventive for pulmonary embolism. Among other therapeutic measures they used stellate infiltration, intravenous injections of procaine and infiltration of the phrenic nerve with anesthetics. Successful results occurred in fewer than 30 per cent. Adams-Ray of Stockholm reported 3 deaths from pulmonary embolism out of 221 cases treated, in comparison with 47 deaths out of 264 case not treated with anticoagulants. Luzuy of Blois encountered 57 cases of embolism in 8,000 patients operated on. He employed ephedrine, morphine and atropine intramuscularly and procaine intravenously.

Acute Intoxication by Carbon Monoxide in the Paris District

In a special issue of the *Semaine des hôpitaux* Léon Binet, dean of the Paris Faculty of Medicine, Michel Conte and Henri Cabau explained that the number of persons poisoned by carbon monoxide has risen from 500 in 1929 to 550 in 1939, 2,000 in 1941 and 3,833 in 1944. The mortality has increased from 249 in 1938 to 1,046 in 1944: 45 per cent for men, 35 per cent for women and 20 per cent for children. The authors find that these cases are due to the imprudence and the negligence of the users, to which is to be added the bad state of the pipes, the bad adjustment of burners and especially in 1944 the use of "tire-gaz" (draw gas) a special apparatus used by consumers to compensate for the lowering of pressure and of heating power due to the shortage of coal. A gas leak is the most dangerous, as the percentage of carbon monoxide in the gas of the city of Paris increased from 13 per cent in 1935-1940 to 20 per cent in 1946 (during the winter of 1944 it rose to 29 per cent). On the other hand the odor of the gas is less conspicuous than before the war. Of 136 cases of poisoning treated by Léon Binet and Michel Conte, 23 patients (13 per cent) died. L. Binet emphasizes the importance of oxygen therapy as long as the coma persists. He also uses camphor injections. These physicians criticize the use of carbon dioxide on patients who breathe well and also the practice of blood-letting. Lumbar puncture is to be practiced cautiously; in 13 cases the meningeal reaction appeared only some days after the poisoning. In serious cases hyperazotemia is the rule and gives an indication of the prognosis.

Penicillin Therapy in Rheumatism

In the center for penicillin therapy for rheumatism at the Cochin Hospital (Paris) F. Coste, L. Auquier and J. Nehbil treated 84 cases of various kinds of rheumatism. They employed penicillin intramuscularly with an average daily dose of 300,000 units for eight to ten days and an average total dose of 2,400,000 to 3,000,000 units. Recently they increased the daily dose to 1,000,000 units for eight to ten days. They confirm the value of penicillin therapy in subacute gonorrheal rheumatism and in many chronic forms. In 16 cases of gonorrheal rheumatism there were 4 excellent results, 6 good, 3 partially good and 3 failures. In 14 cases of infectious rheumatism, postanginal, postgrippal and postscarlatinal results were 1 excellent, 6 good, 3 partial and 4 failures. In 26 cases of chronic polyarthritis there were 7 good results and 19 failures.

Conservative Operation for Cancer of the Rectum

At the forty-ninth congress of the French Association of Surgery d'Allaine and Vernejoul reported the results of an operation for removing high tumors of the rectum by the abdominal-sacral route, in which the sphincter apparatus was conserved. Low tumors were removed by the abdominal-perineal approach. A temporary artificial anus was employed which is kept open for two or three months.

Treatment of Herpes Zoster by Globulins of Varicella Convalescents

At a meeting of the Société des Hopitaux of Algiers, Zermati and Mutin report in 2 new cases of rapid cures of herpes zoster by varicella globulins. This confirms the observations on 2 cases already reported by Benhamou in a recent paper on the globulin therapy of infectious diseases.

George Baigerie Jobson ⊕ Franklin, Pa.; Harvey Medical College, Chicago, 1900; specialist certified by the American Board of Ophthalmology, American Board of Otolaryngology and the American Board of Plastic Surgery; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; past president of the Venango County Medical Society; served as a member and president of the board of education; affiliated with Oil City Hospital; died October 21, aged 77, of myocarditis.

Helen Jeffery Kelly, Milwaukee; University of Minnesota Medical School, Minneapolis, 1939; interned at Swedish Hospital in Minneapolis; diplomate of the National Board of Medical Examiners; formerly connected with the Kentucky State Board of Health in Louisville; died October 29, aged 43, of accidental barbiturate poisoning.

Arthur Samuel Kitchen ⊕ Escanaba, Mich.; University of Toronto Faculty of Medicine, Toronto, Canada, 1899; fellow of the American College of Surgeons; past president of the Delta County Medical Society; served as a member of the city council; on the staff of St. Francis Hospital; died October 30, aged 71, of coronary occlusion.

Edward Newton Lillard, Madison, Va.; Medical College of Virginia, Richmond, 1901; member of the American Medical Association; died October 9, aged 74, of carcinoma of the throat.

Wilbur Wallace McCleary, Remer, Minn.; Chicago Medical College, 1889; died October 22, aged 79, of coronary occlusion.

Robert Sherwood McGeachy, New Bern, N. C.; Bellevue Hospital Medical College, New York, 1894; member of the American Medical Association; served during World War I; health officer of Craven County since 1939; formerly health officer of other counties; died in St. Luke's Hospital October 9, aged 74, of burns received when a gas water heater exploded in the basement of his home.

Ady Royal McKeown, Letts, Iowa; University of Colorado School of Medicine, Denver, 1911; served during World War I; died in the University Hospital, Iowa City, October 29, aged 63, of gunshot wounds.

Acute Intoxication by Carbon Monoxide in the Paris District

In a special issue of the *Semaine des hopitaux* Leon Binet, dean of the Paris Faculty of Medicine, Michel Conte and Henri Cabau explained that the number of persons poisoned by carbon monoxide has risen from 500 in 1929 to 550 in 1939, 2 000 in 1941 and 3,833 in 1944 The mortality has increased from 249 in 1938 to 1,046 in 1944 45 per cent for men, 35 per cent for women and 20 per cent for children The authors find that these cases are due to the imprudence and the negligence of the users, to which is to be added the bad state of the pipes, the bad adjustment of burners and especially in 1944 the use of "tire-gaz" (draw gas) a special apparatus used by consumers to compensate for the lowering of pressure and of heating power due to the shortage of coal A gas leak is the most dangerous, as the percentage of carbon monoxide in the gas of the city of Paris increased from 13 per cent in 1935 1940 to 20 per cent in 1946 (during the winter of 1944 it rose to 29 per cent) On the other hand the odor of the gas is less conspicuous than before the war Of 136 cases of poisoning treated by Leon Binet and Michel Conte, 23 patients (13 per cent) died L Binet emphasizes the importance of oxygen therapy as long as the coma persists He also uses camphor injections These physicians criticize the use of carbon dioxide on patients who breathe well and also the practice of blood-letting Lumbar puncture is to be practiced cautiously, in 13 cases the meningeal reaction appeared only some days after the poisoning In serious cases hyperazotemia is the rule and gives an indication of the prognosis

Penicillin Therapy in Rheumatism

In the center for penicillin therapy for rheumatism at the Cochin Hospital (Paris) F Coste, L Auquier and J Nehbil treated 84 cases of various kinds of rheumatism They employed penicillin intramuscularly with an average daily dose of 300 000 units for eight to ten days and an average total dose of 2,400,000 to 3,000,000 units Recently they increased the daily dose to 1,000,000 units for eight to ten days They confirm the value of penicillin therapy in subacute gonorrheal rheumatism and in many chronic forms In 16 cases of gonorrheal rheumatism there were 4 excellent results, 6 good, 3 partially good and 3 failures In 14 cases of infectious rheumatism, postanginal, postgrippal and postscarlatinal results were 1 excellent, 6 good, 3 partial and 4 failures In 26 cases of chronic polyarthritis there were 7 good results and 19 failures

Conservative Operation for Cancer of the Rectum

At the forty ninth congress of the French Association of Surgery d Allaine and' Vernejoul reported the results of an operation for removing high tumors of the rectum by the abdominal sacral route in which the sphincter apparatus was conserved Low tumors were removed by the abdominal perineal approach A temporary artificial anus was employed which is kept open for two or three months

Treatment of Herpes Zoster by Globulins of Varicella Convalescents

At a meeting of the Societe des Hopitaux of Algiers Zermati and Mutin report in 2 new cases of rapid cures of herpes zoster by varicella globulins This confirms the observations on 2 cases already reported by Benhamou in a recent paper on the globulin therapy of infectious diseases

New Method of Cervicocystopexy

Perin employed a method of closing the urethrovesical angle by fixing the neck and anterior wall of the bladder to the anterior wall of the abdomen for urinary incontinence of women. He reported good results in 30 cases kept under observation for a long period.

Repair of Nervous Tissue

Merle d'Aubigne, Wertheimer and Dejardin stated that autografts give the best results in the repair of exposed nerves of the limbs. Petit Dutaillis obtained good results in 40 per cent of such injuries by using heterografts taken from dogs.

Miscellaneous

Professor Lucienne Random, specialist in research on food, has been elected a member of the Academy of Medicine.

Among the deputies elected November 10 in the new French Parliament were 20 physicians belonging to various political parties.

In agreement with the Ministry for Public Health the French Red Cross put into execution the plan of traveling consultations for nurslings for the rural communities by means of lorries specially fitted for the purpose.

THE NETHERLANDS

(From Our Regular Correspondent)

AMSTERDAM, Dec. 4, 1946.

Recent Developments in Biochemistry

British biochemists, accepting an invitation extended to them by six scientific societies, came to the Netherlands to lecture on November 8 and 9 on recent developments. The meetings were held in the physiologic laboratory of the University of Utrecht. Dr. E. Barton Wright gave a survey on the microbiologic assay of amino acids. He pointed out that ten amino acids are essential for mammalian nitrogen metabolism, according to Rose, and that these and six other amino acids, together with the components of the vitamin B complex, can be estimated by using convenient micro-organisms, bacteria and fungi. Using lactic acid-producing bacteria the lactic acid production is proportional to the concentration of vitamin in the medium. A similar principle applies to the amino acids. Among other advantages, the microbiologic assay affords an easy parallel estimation of essential amino acids whose separation and chemical estimation is still troublesome.

Dr. D. P. Cuthbertson discussed the respective importance of the quality and quantity of protein and its bearing on food, work, blood, organic function, disease, trauma and the healing of wounds.

Prof. A. C. Chibnal surveyed recent research on the chemistry of the protein molecule. He pointed out that by physical methods protein molecules can be studied without destruction, whereas analytic chemistry approaches the problem by resolving the giant molecules into their components. An attempt can then be made to elucidate the links, keeping these components together. Partition chromatography, bacterial enzymes and microbiologic assay are the principal new methods employed for the assay of amino acids in extremely small quantities of material. Improvements are still desirable in the methods for the estimation of monoamino acids, since the utmost accuracy is required for the analysis of protein structure based on these estimations. Analyzing the insulin molecule Chibnal found data suggesting that the submolecule has a molecular weight of 12,000 and three or four of these submolecules are likely to constitute the protein molecule itself. There are four peptide chains in such submolecules, with two terminal glycyl and two phenylalanyl residues, while the component chains are linked together by disulfide bridges. The protein edestin consists of six submolecules of a molecular weight of 50,000, long peptide chains carrying terminal glycine residues. Structural analyses revealed the existence of various hemoglobins.

Prof. W. T. Astbury described recent advances in roentgenologic and related studies of the fibrous proteins. The constituent proteins of keratin, myosin, fibrinogen and epidermis and of collagen, epidermin and tropomyosin are now known both in crystalline and in fibrous form. The two forms are distinguished by their physical properties, fundamental for the physiologic role played by these proteins in coagulation, muscular action and elasticity of microscopic structures. In addition to roentgen ray analysis, the electron microscope aided recent advance also with reference to the relation between the proteins, the polysaccharides and the nucleic acids.

Dr. A. J. P. Martin gave an account of his method of partition chromatography of amino acids and peptides. Essentially the method consists in spreading out an amino acid solution over filter paper by using two immiscible solvents and spotting the substances over the whole surface by the use of an indicator that acts as a kind of developer. Less than a milligram of protein is needed for a qualitative analysis made in this way. Small peptides are similarly analyzed, and the analysis of gramicidin S was used as an example to illustrate the prospects of the new technic. Another method consists in electrophoresis through solid jelly, by which a kind of spectral band arises out of the various components of an amino acid mixture.

Phase Contrast Microscopy

Prof. F. Zernike, physicist of the University of Groningen, ten years ago developed the principle of this new approach to microscopic research, permitting the study of unstained even of living, cells. Small differences in the fraction of light beams are *revealed by sharp contrast under suitably adjusted* microscopes. It is possible to observe nuclei, cytoplasmic constituents, chromosomes, cell division and the part played by the cell constituents during various phases of life. A most instructive film was discovered in Germany by Colonel Bright of the United States Army. It showed the maturation processes of the female and male gametes of grasshoppers. This film was shown to students and to some members of the staffs of various universities in the Netherlands during November. The film showed vividly the fundamental importance of the discovery of Zernike and at the same time proved the research and instructive value of the phase contrast procedure.

Vital Statistics

A sharp rise in births and marriages and satisfactory rates of morbidity, mortality and infant mortality are revealed by a report of *the bureau of statistics in the Netherlands* during the third quarter of the current year. Doctors and pharmacists refuse to maintain their contracts with the health insurance funds without a thorough revision of their respective positions as *regards fees and regulations.* It is emphatically stated that the health services to patients will not be affected by the discussion of these organizational problems.

The introduction of the eight hour work day for nurses in Amsterdam municipal hospitals is expected to contribute to the solution of the standing problem in nursing. A reduction of the hours on duty will make this responsible occupation more attractive.

Personal

Dr. M. J. L. Dols has been appointed to a newly established chair of Popular Nutrition in the University of Amsterdam. He has gained ample experience on this subject while acting as adviser of the Ministry of Agriculture, Fishery and Food.

Bureau of Investigation

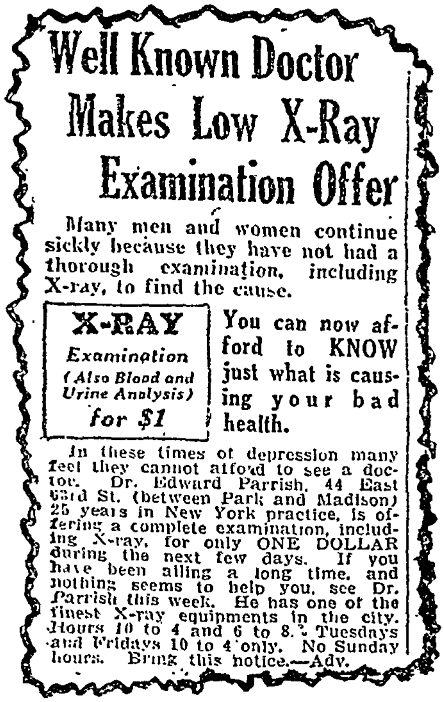
DR. PARRISH'S FRAUDS PERISH

Post Office Bans His "Cures" for Overweight and Underweight from the Mails

Two fraud orders issued by the Post Office Department in recent months against the mail-order activities of Edward Parrish, M.D., of New York indicate that he cared little whether his right hand knew what his left hand was doing. For some ten years Parrish was advertising "Cal-Par" for reducing; he did not, however, neglect the green pastures on the other side of the fence; he also promoted a nostrum for weight-building called "Dr. Parrish's Prescription B-7." The nostrums advertised as "doctor's prescription," a catch phrase calculated to impress the public, have been legion.

Dr. Parrish was born in Philadelphia in 1873, graduated from Long Island College of Medicine, Brooklyn, in 1898, licensed in New York in the same year and in New Jersey in 1915 by endorsement of his New York credentials. He has apparently lived in a dozen different cities and towns in these two states. Presumably he practiced medicine in most of these places, apparently entering the "patent medicine" business only in later years, though old records show a Dr. Edward Parrish as a testimonial writer for several proprietary products, including one for "Castoria" which appeared in a Chicago newspaper as long ago as 1906.

According to Utica, N. Y., papers in 1918, charges had been brought against Dr. Edward Parrish, then of that city, with the object of having his license revoked by the state. The papers reported that a grand jury, after hearing the charges, brought an indictment charging petty larcency. It was afterward shown that the grand jury had no power to find an indictment for petty larceny. Parrish, who had apparently been an advertiser, seems to have diagnosed a number of perfectly healthy patients as being ill and requiring a considerable expenditure of money and time to be "cured."



Well Known Doctor Makes Low X-Ray Examination Offer

Many men and women continue sickly because they have not had a thorough examination, including X-ray, to find the cause.

X-RAY
Examination
(Also Blood and Urine Analysis)
for $1

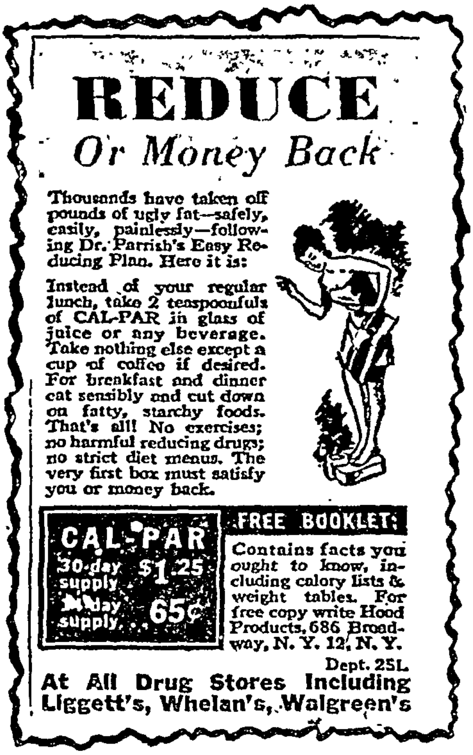
You can now afford to KNOW just what is causing your bad health.

In these times of depression many feel they cannot afford to see a doctor. Dr. Edward Parrish, 44 East 63rd St. (between Park and Madison) 25 years in New York practice, is offering a complete examination, including X-ray, for only ONE DOLLAR during the next few days. If you have been ailing a long time, and nothing seems to help you, see Dr. Parrish this week. He has one of the finest X-ray equipments in the city. Hours 10 to 4 and 6 to 8. Tuesdays and Fridays 10 to 4 only. No Sunday hours. Bring this notice.—Adv.

Parrish's advertisement in a cheap tabloid (1931).

While in Utica, Edward Parrish carried large advertisements in the newspapers, in one of which, in 1920, he offered "One Dollar Examination to the Sick, Using the Wonderful X-Ray." (By 1920 a good part of the public must have become blasé about the "wonders" of this ray, which had then been known for all of 25 years). In 1931 Parrish was playing up his "Low X-Ray Examination Offer" to the public, as shown by an advertisement reproduced on this page and taken from a cheap tabloid.

Then Parrish went into the "reducing" business in New York, playing up "Cal-Par Reducing Plan" under the trade style Cal-Par Corporation. The product "Cal-Par" sometimes bore other company names, such as Hood Products Corporation and Hood-lax Corporation. The last-named concern also sold "Hoodlax," promoted by Victor Lindlahr, whose activities in the food-fad and nostrum fields were dealt with in this department of THE JOURNAL March 24, 1945, page 733, in connection with "Serutan."



REDUCE
Or Money Back

Thousands have taken off pounds of ugly fat—safely, easily, painlessly—following Dr. Parrish's Easy Reducing Plan. Here it is:

Instead of your regular lunch, take 2 teaspoonfuls of CAL-PAR in glass of juice or any beverage. Take nothing else except a cup of coffee if desired. For breakfast and dinner eat sensibly and cut down on fatty, starchy foods. That's all! No exercises; no harmful reducing drugs; no strict diet menus. The very first box must satisfy you or money back.

CAL-PAR
30-day supply $1.25
[illegible]-day supply 65¢

FREE BOOKLET:
Contains facts you *ought to know*, including calory lists & weight tables. For free copy write Hood Products, 686 Broadway, N. Y. 12, N. Y.
Dept. 25L

At All Drug Stores Including Liggett's, Whelan's, Walgreen's

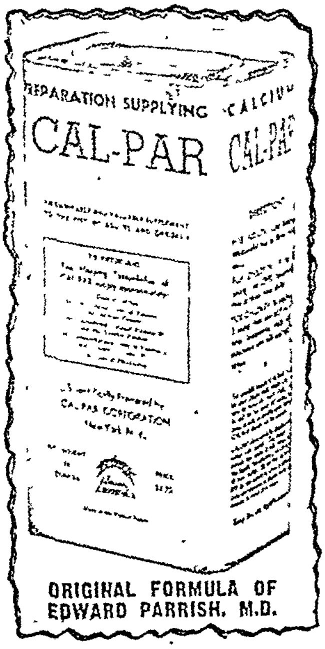
Newspaper advertisement (1946).

In December 1937 Parrish was sending out form-letters with the offer: "For only five dollars I will ship you one half dozen Cal-Par, $1.25 size, and enter a one year's subscription at once for SUCCESSFUL LIVING in your name." This was signed "Edward Parrish, M.D., Editor" and was on the letterhead of "Successful Living—The Publication of Modern Living Health Institute, Psychology Institute of America." There was also the statement: "Official Organ, Body and Mind Foundation, Edward Spencer Cowles, M.D., Founder and Director."

According to a leaflet promoting both Hood-Lax and Cal-Par, the latter nostrum partly originated with Parrish's physician-grandfather, another Edward Parrish. The circular went on to say: "The present formula of Cal-Par was evolved by [the current] Dr. Edward Parrish from his grandfather's old formula as a result of his own practices and researches, and in collaboration with well-known chemists and scientists." Further, the circular described Parrish as "the editor of Modern Living Magazine." This was another of the jobs for a time filled by Victor Lindlahr, previously mentioned. The magazine was largely given over to fads in foods and medicine.

It is interesting to note the actual composition of Cal-Par, the perfecting of which required "collaboration with well-known chemists and scientists"—so "well known," indeed, that Parrish seems to have thought it unnecessary to divulge their identities. A specimen taken from an interstate shipment declared misbranded under the federal Food, Drug and Cosmetic Act in 1943 was reported by government chemists to contain wheat germ, wheat bran, crystalline material and wheat flour. A more detailed list of ingredients was given on the label of the package of Cal-Par involved in the Post Office investigation, which stated, "Active ingredients: wheat embryo (wheat germ), calcium phosphate, calcium carbonate, irradiated yeast, fish liver oil and iron phosphate . . . skillfully compounded with sugar, calcium hypophosphite, calcium glycero-phosphate, calcium lactate and flavoring." Also, there was the claim: "A special dietary product for adults and children."

Cal-Par seems to have been promoted less as a "special dietary product" than as a weight reducer. A 1946 advertisement of it as such is reproduced in this article. Here it is presented as "Dr Parrish's Easy Reducing Plan," with a dietary regimen recommending 2 teaspoonfuls of Cal-Par in any beverage as a substitute for lunch. If the user followed the additional advice given—"for breakfast and dinner eat sensibly and cut down on fatty, starchy foods"—he doubtless would reduce anyhow, without benefit of Cal-Par.



From an advertisement in "Physical Culture" (1938).

The Post Office found that a reader of the Cal-Par advertisements might easily be misled by the assurances, "Reduce 3 to 5 pounds a week yet eat plenty," "You needn't suffer a single hungry moment," and the like, into thinking that he could reduce substantially without any privation or great change in his eating habits. The Post Office hearing also brought out that any resultant weight reduction would be due, not to taking Cal-Par, but to the restricted food intake recommended. Furthermore, expert medical witnesses for the government testified that there could be danger in a person's reducing the promised 3 to 5 pounds per week without evidence from a physical examination that he was fit for such reduction, and also without a physician's supervision of the "course" The business, under the names Cal-Par and Cal-Par Corporation, was declared to be a fraudulent enterprise and was accordingly debarred from the mails on March 8, 1946 Because the concern was receiving only two letters a day addressed to Dr. Parrish himself, his name was omitted from the fraud order, with the provision that one would be issued against him if later he should be found to be conducting the business under his name. The 1946 Cal-Par advertisement reproduced here shows that the product may now be obtained in drug stores, and a booklet on calories and weight tables from Hood Products, New York, by mail.

It was against Edward Parrish himself and the Parrish Medicine Company of New York that another fraud order was issued less than a month later—on April 4, 1946. Theirs was the business, not of reducing weight, but of increasing it, through their "Prescription B-7." In this case Parrish apparently did not claim to be using a "prescription" from his physician-grandfather. Hardly, for the vitamins declared on the label were not known in his grandfather's day. The said label called the preparation "a dietary supplement" and further stated:

> "Each level teaspoonful contains (approximately)
> Malt Diastase... Iron Pyrophosphate 1½ gr.
> Sucrose ....Tribasic Calcium Phosphate 5½ gr.
> Cocoa ....B_1 (Thiamine Hydrochloride) 2 mg.
> Vanillin ....B_2 (Riboflavin) 0.5 mg.
> Vitamin D—135 Units"

The directions called for "1 level teaspoonful, 3 times daily, after meals, in a glass of water or cold milk." The user also was advised to get nine or ten hours' sleep regularly, rest before and after each meal, eat between meals, avoid over-exercise, walk slowly, sit rather than stand when working, and "eat more concentrated, starchy foods, and fatty foods." One might suppose that even the man in the street would know that these procedures would tend to correct underweight if the condition was not due to organic or systemic disease, regardless of any added "prescription," but the promoters would not want to hurt their business by pointing out that fact.

At the hearing of this case the government introduced expert medical testimony showing that at least 50 per cent of all underweight cases are due to systemic disorders and would not be helped by the use of this nostrum or any other, and hence in such cases Prescription B-7 would not produce the "better, healthier figure" promised to all in the advertising. The testimony further showed that there are numerous and varying causes of underweight, including bad habits in sleeping, eating, drinking, smoking and other excesses, as well as overwork, worries and fears, and allergies to certain foods, the latter causing their victims to become food faddists and more or less starve themselves. Hence, the government's medical witness testified, there can be no one treatment that will remove all of the many diseases and other conditions causing underweight. Nevertheless, it was pointed out, Parrish's advertising was addressed to all underweight persons, making no exceptions in offering "the Doctor's own proven method" for gaining weight which "will show you how to fill out your figure" and promising that "you will usually begin to gain from 2 to 3 ounces daily."

The business was accordingly adjudged a scheme to swindle the public, and was debarred from the mails, as previously mentioned.

A prophet without honor in his own bailiwick seems to have been Parrish's lot for a time. The New York State Department of Health, in the May 3, 1943, issue of its official weekly, reported that in the previous year a communication had been sent to Parrish, informing him that the reference to him in an "obesity cure" advertisement (presumably Cal-Par) as "Former Health Officer, State of New York," was misleading, in potentially giving the impression that he had been a state officer. The fact was that he had merely been health officer of an upstate village some 20 years before.

The New York State Board of Medical Examiners found Parrish guilty of advertising and, on July 26, 1946, notified him that his license to practice medicine in that state had been suspended for the six months following that date.

Now the nostrum business that Parrish operated under his own name is banned from the mails, but perhaps he will attempt to continue it by thinking up a new trade style. Meantime the Hood Products, New York, has advertised that Cal-Par is now obtainable in drug stores, and so this imposition on the public credulity persists.

MEDICAL EDUCATION AND LICENSURE

Forty-Third Annual Congress on Medical Education and Licensure, to be held in the Red Lacquer Room, Palmer House, Chicago, February 9 to 11, 1947

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS, AMERICAN MEDICAL ASSOCIATION

Monday Morning, February 10, 9:30

H. G. Weiskotten, M.D., *Presiding*

Current Problems in Medical Education
H. G. Weiskotten, M.D., Syracuse, N. Y., Dean, Syracuse University College of Medicine; Chairman, Council on Medical Education and Hospitals, American Medical Association

Residency Programs in Veterans Hospitals
Round Table Discussion Moderator. C. Gordon Heyd, M.D., New York, Member, Council on Medical Education and Hospitals
Discussants: Paul R. Magnuson, M.D., Washington, D. C., Director of Research and Education, Veterans Administration; Harold S. Diehl, M.D., Minneapolis, Dean, University of Minnesota Medical School; Tinsley R. Harrison, M.D., Dallas, Texas, Professor of Internal Medicine, Southwestern Medical College; J. Roscoe Miller, M.D., Chicago, Dean, Northwestern University Medical School, and Burrell O. Raulston, M.D., Los Angeles, Dean, University of Southern California School of Medicine
General Discussion

Medicine and National Security
Edward L. Bortz, M.D., Philadelphia, Chairman, Committee on National Emergency Medical Service, American Medical Association
Discussion led by Harvey Stone, M.D., Baltimore, Associate Professor of Surgery, Johns Hopkins University School of Medicine, and Harold C. Lueth, M.D., Omaha, Dean, University of Nebraska College of Medicine

Monday Afternoon, 2:00

H. G. Weiskotten, M.D., *Presiding*

Academic Performance of Premedical Veterans
Raymond R. Paty, M.A., LL.D., L.H.D., Atlanta, Ga., Chancellor of the University System of Georgia
Discussion led by Merle Coulter, Ph.D., Chicago, Professor of Botany, University of Chicago; formerly head, Biology Branch, Shrivenham American University, Shrivenham, England

The Hospital Survey and Construction Act
Thomas Parran, M.D., Washington, D. C., Surgeon General, United States Public Health Service
Discussion led by Graham Davis, Battle Creek, Mich., Director, Division of Hospitals, W. K. Kellogg Foundation, Member, Federal Hospital Council

Responsibilities of a Medical School to a Community
James A. Greene, M.D., Houston, Texas, Professor of Medicine, Baylor University College of Medicine
Discussion led by Roy R. Kracke, M.D., Birmingham, Ala., Dean, Medical College of Alabama

Medical Applications of Atomic Energy
Reuben G. Gustavson, Ph.D., D.Sc., L.H.D., Lincoln, Neb., Chancellor, University of Nebraska
Discussion led by Raymond E. Zirkle, Ph.D., Chicago, Director, Institute of Radiobiology and Biophysics, University of Chicago

Monday Afternoon, 5:30

RECEPTION GIVEN TO REGISTRANTS OF THE CONGRESS BY THE AMERICAN MEDICAL ASSOCIATION FOR H. G. WEISKOTTEN, M.D.

Room Fourteen

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Dec. 28, page 1105.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part III.* Chicago, Jan. 9-11. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written. Part I.* Various centers, Jan. 17. *Oral.* Los Angeles, April 11-12. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York.

American Board of Dermatology and Syphilology: *Written.* Various centers, March 24. Final date for filing application is Feb. 17. *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Written.* Chicago, March 17. *Oral.* Chicago, April 24-26. Final date for filing application is Feb. 15. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Neurological Surgery. *Oral.* Examination to be given during the Summer. Applications for examination will be accepted until Feb. 15. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago.

American Board of Obstetrics and Gynecology: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: *Oral. All Groups. Parts I and II.* Chicago, October 1947. Final date for filing application is March 1. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Me.

American Board of Otolaryngology: *Oral.* St. Louis, April 16-19. Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Contracts: Hospital's Failure to Furnish Hospital Services—Good Faith of Staff Physicians.—The plaintiff sued for damages alleged to have resulted from the refusal of the defendant hospital to furnish hospital services to which plaintiff's wife claimed to be entitled. From a judgment in favor of the plaintiff the defendant appealed to the court of appeals of Alabama.

The defendant hospital entered into a contract with the De Bardeleben Coal Company under the terms of which it agreed to furnish hospitalization to the coal company's employees and their families. Among other things, the contract provided:

> No employee or any member of his family shall be admitted to the hospital (other than in accident cases) except upon written request of the doctor regularly employed by the Corporation or the patient's family physician.
>
> Upon such written request of the attending physician a member or members of the "STAFF" shall examine all applicants for hospitalization in order to determine whether or not hospitalization is necessary, or whether or not the disease or condition is such as is included or excluded from the hospital under the terms of this contract. In the event it should be excluded from the hospital under the terms of this contract or it is determined that no hospitalization is necessary, the "STAFF" will advise the employee and/or his family and/or his attending physician the diagnosis and findings revealed by said examination in order that the employee and/or his family may be properly treated by his own physician.

One of the regularly employed physicians of the coal company attended the plaintiff's wife and in the course of his treatment referred her to the defendant hospital on June 1, 1944. On her arrival at the clinic of the hospital she was given a physical examination by Dr. Anderson, one of the staff physicians, and Dr. Carraway, chairman of the board of directors of the institution. Dr. Anderson reported back to the company physician that the patient did not require hospitalization at that time and recommended a treatment for her to follow, with instructions to return in ten to fourteen days. She returned, feeling no better, on June 19. Again she was examined, again defendant was of the opinion that no hospitalization was needed and again she was advised to take a course of treatment and to return at a later date if no improvement was shown. Instead of returning to the defendant a third time, however, the plaintiff's wife went to another physician, who advised hospitalization. On June 22 she was admitted to another hospital, where she remained about twenty days and underwent an operation for the removal of her uterus. She testified that she has felt fine since the operation.

The defendant first argued that the evidence does not sustain the necessary proof that there was a demand for performance on the part of the plaintiff or his wife or a refusal to perform on the part of the defendant. Under the terms of the contract this is a condition precedent to a right of action for its breach. The jury was privileged, said the court, and it was its duty, to consider all the facts and circumstances disclosed by the evidence in its effort to find whether or not there was a demand for performance and a refusal thereof. This inquiry would include a consideration of the conduct of the parties involved. It cannot be successfully contended, said the court, that a formal demand or refusal was required. If it was made known to the hospital authorities that hospitalization was expected, and the course of action of the authorities was such that the jury could reasonably infer that hospitalization was denied, these essential conditions would have been met. In support of the plaintiff's case the following testimony of his wife appeared:

> Q. Did you ask to be admitted to the hospital at that time; that is, on the 19th of June? A. Yes, sir, I did.

The defendant also argued that, since the contract in question provides that the hospital staff shall determine whether or not hospitalization is necessary or required, plaintiff is precluded from inquiring into the good faith of the decision so made and is compelled to accept its judgment as final and conclusive of the right to claim a breach of the contract to furnish hospitalization. The court of appeals said that it is a court's duty to adhere to the express stipulations of a written agreement and not change by implication the manifest intention of the contracting parties. This responsibility of the court must, however, yield to a reasonable construction in an effort to secure and safeguard the real intention of the parties in the light of their mutual understandings and the objects and rights intended to be accomplished and protected. The court said it had been unable to find any case construing a contract exactly like the instrument here involved. However, in a case in which a contract obligated one of the contracting parties to furnish labor or material, payment therefor being based on the contigency that the recipient of the services or the purchaser of the goods be satisfied, the court has said:

> So, where, by the terms of a contract to do a piece of work or perform services, the excellence of which is not a mere matter of taste or fancy, or to furnish a piece of machinery or other articles the suitableness of which involves a question of mechanical fitness to do certain work or accomplish a certain purpose, the one party warrants the work or article to be satisfactory to the other, the weight of authority is, though the cases are not entirely harmonious, that there can be no recovery when the employer or purchaser is in good faith dissatisfied.

The contract in this case is not different in principle and a contrary construction would afford opportunity for one contracting party to strike down at will benefits intended to be conferred by the written instrument. It is reasonable to assume that this was not the intention but that the parties were dealing on the basis of justice and fairness. In conclusion, the court said that, considering all the evidence as disclosed by the record and the reasonable inferences that may be drawn therefrom, the lower court properly submitted this issue to the jury. The judgment of the lower court in favor of the plaintiff was affirmed.—*Norwood Hospital, Inc., v. Howton, 26 So. (2d) 427 (Ala., 1946).*

Medical Practice Acts: Distinction Between Prescription and Sale in Relation to Revocation of License for Unlawful Sale of Narcotic Drugs.—The petitioner was convicted in a federal court of unlawful sale of morphine sulfate in that he prescribed such drug to an addict, the prescription being filled by a druggist in good faith without knowledge that the prescription was unlawfully used. Accordingly the Board of Regents revoked the petitioner's license to practice medicine. This action of the board was upheld by the Supreme Court, appellate division, on the theory that a sale and prescription were the same thing (*Tonis v. Board of Regents of University of State of New York*), 58 N. Y. S. (2d) 766, J. A. M. A. **130:**818 [March 23] 1946). From such adverse ruling, the petitioner appealed to the court of appeals of New York.

The Education Law justifies the revocation of a license to practice medicine for a conviction of an act constituting a felony under the laws of the state of New York. While the "sale" of a habit-forming drug is a felony, "to prescribe" taken alone is merely a misdemeanor. Respondent argued however that, while petitioner would have been guilty of a misdemeanor if no sale had followed, still, since a sale was made (although by an innocent person, the druggist), the act of prescribing became a felony because the petitioner thus participated in a sale. The argument, said the court, might be persuasive under the internal revenue code, where there is no differentiation between "sell" and "prescribe"; the New York law, however, follows a definite plan. Public health law section 422 lists eight prohibited acts. The unlawful issuance of a prescription by a physician is to "prescribe," as indicated in sections 422 and 427. It is not to "sell," as prohibited in section 422 and defined in section 421, subdivision 10. To hold otherwise, said the court, would be to remove the word "prescribe" from section 422, despite the fact that the legislature has written it in alongside the word "sell."

Accordingly the ruling of the Appellate division was reversed and the matter remitted to the Board of Regents for further proceedings.—*Tonis v. Board of Regents of University of State of New York, 67 N. E. (2d) 245 (N. Y., 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. *Requests should be accompanied with stamps* to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Effect of Salicylates on Acute Rheumatic Fever.—Warren and his co-workers observed acute rheumatic fever in 186 young adults under three different therapeutic regimens. Some were treated with small doses of salicylate given only to relieve symptoms. Others received large doses by mouth until all evidence of rheumatic activity had subsided. A third group received sodium salicylate intravenously for one week followed by large oral doses. The use of sodium salicylate in amounts of 10 to 16 Gm. per day reduces the temperature more quickly in acute rheumatic fever than do small doses. Large doses are advantageous in the treatment of acute rheumatic pericarditis. Doses of 10 to 16 Gm. per day will not prevent the development of cardiac damage or the progression of preexisting heart disease. Large doses will not shorten the period of rheumatic activity any more than small amounts, and they will not prevent the development of polycyclic attacks of rheumatic fever. The routine use of sodium salicylate by intravenous infusion is not warranted by the evidence presented to obtain a rapid elevation of the plasma salicylate level, to maintain a high plasma level or to affect the fever or sedimentation rate. If large amounts of salicylate are given either orally or intravenously the premonitory signs of toxicity must be recognized early and the dose must be reduced to prevent progression of the symptoms. The use of large amounts of salicylate may offer some advantage in the first weeks of therapy and may bring about a rapid reduction of the fever and alleviation of the symptoms, but the continued administration of large amounts of this drug until the sedimentation rate is normal is of questionable value.

Refractory Case of Subacute Bacterial Endocarditis.—Loewe and his associates report a case of subacute endocarditis due to Veillonella gazogenes. Massive doses of sulfonamides were ineffective. Twelve courses of penicillin therapy of varying length, combined at times with adjuvants such as sulfonamides and heparin, failed to sterilize the blood stream, although progress of the infection was retarded during the year of this treatment. Dosages of penicillin up to 10 million units per day by the continuous intravenous route were nontoxic and well tolerated. A total of 466,670,000 units of penicillin was used during this period. In vitro studies revealed bacteriostasis for the organism at 10 units of streptomycin and penicillin per cubic centimeter. The minimum lethal dose was 10 units per cubic centimeter and 30 units per cubic centimeter respectively for streptomycin and penicillin. With a constant concentration of 10 units per cubic centimeter of penicillin, the bacteriostatic and minimum lethal dose of sodium para-aminohippurate was 16 mg. and 63 mg. respectively per hundred cubic centimeters. This contrasts with bacteriostatic and lethal doses of 40 mg. and 163 mg. respectively of sodium para-aminohippurate alone per hundred cubic centimeter. With concentrations of sodium para-aminohippurate varying from 20 to 50 mg. per hundred cubic centimeters the minimum lethal dose of penicillin against the infecting organism was lowered as much as 15 units per cubic centimeter. These data were clinically applied with satisfactory results by the simultaneous daily intravenous administration of penicillin and sodium para-aminohippurate in doses of 10 million units and 240 Gm. respectively over a period of sixteen days. Heparin was also incorporated. This is the first case in which sodium para-aminohippurate has been used with penicillin in the clinical arrest of an infection otherwise highly resistant to the action of penicillin alone.

Renin in Essential Hypertension.—Taquini and Fasciolo used the indirect method of Muñoz and his associates for the detection of renin. This method is capable of detecting about 0.1 unit of human renin in 10 cc. of plasma. Its sensitivity is from five to ten times greater than the direct method of Leloir and his co-workers. The authors made their studies on 23 hypertensive patients with and without impairment of renal function. They were unable to detect renin in the arterial or venous plasma of these patients. They feel that these findings do not disprove the renal origin of human hypertension. Actually, renin has been detected in the plasma of dogs after a short period of complete ischemia of the kidney, and in the renal and arterial blood in the acute phase of hypertension produced by partial but severe ischemia of the kidney. Renin has not been demonstrated in the renal or arterial blood of chronically hypertensive dogs. In human beings small amounts of renin were found in the renal vein after a short period of complete ischemia and in the acute hypertension of a few cases of eclampsia and fulminating glomerulonephritis but not in chronic hypertension. The fact that it has not been possible to detect renin in the blood of chronically hypertensive dogs or of patients with essential hypertension neither supports nor negates the hypothesis that renin is the pressor substance involved. Since renin is found by existing methods in the acute phase of renal hypertensive disease and in complete ischemia of the kidney but not in the chronic stage of the disease, the possibility exists that renin may appear in the blood as an autolytic product of the kidney. It is also possible that renin may initiate the pressor mechanism, which later proceeds without its presence.

Potassium Intoxication.—According to Finch and his associates too low or too high concentrations of serum potassium interfere with muscle contraction. Accumulation of potassium in the human body is lethal when it reaches a level in the serum of about 10 to 10.5 miliequivalents per liter (39 to 41 mg. per hundred cubic centimeters), owing to its effect on the myocardium. Potassium intoxication results in widespread impairment of neuromuscular function. It produces a characteristic sequence of electrocardiographic changes, impaired contraction of the heart recognizable by auscultation, and final arrest of the heart in diastole. Flaccid paralysis may also be present, involving the extremities and to a lesser degree the trunk but sparing the cranial nerves for the most part. Two cases with elevation of serum potassium manifesting this clinical syndrome are described. Following administration of sodium chloride, both paralysis and electrocardiographic changes reverted toward normal.

Endocarditis Caused by Streptococcus S. B. E.—Loewe and Alture-Werber deal with the clinical manifestations caused by infection with Streptococcus s. b. e., with particular reference to the increased mortality resulting from its resistance to therapy. In a consecutive unselected series of 115 cases of subacute bacterial endocarditis due to nonhemolytic streptococci treated with a combination of penicillin and heparin, Streptococcus s. b. e. was identified as the etiologic agent in 40 of the 68 patients in whom the infecting organism was classified. A large majority of the patients infected with Streptococcus s. b. e. proved to be refractory to penicillin in standard dosage although the organism was readily inhibited by penicillin in vitro. A comparison of type of streptococcus, in vitro penicillin sensitivity, treatment statistics and outcome indicates the futility of predicting the clinical response without knowledge of the presence or absence of Streptococcus s. b. e., which was in a large measure responsible for the treatment failures and fatalities in this series of 115 cases. All 6 recurrences were due to this organism, as were all 4 intracranial hemorrhages. Whenever the presence of this organism is suspected, a dosage of penicillin at a level of at least 2 million should be established for a span of not less than eight weeks. Persistence with lesser dosages invites failure.

Radiophosphorus in Primary Polycythemia.—Primary polycythemia appears to be an acquired disease in which there is a hyperplasia of the marrow and an abnormal increase of the total blood volume as well as elevated red blood cell, white blood cell and platelet levels in the peripheral blood. Associated findings are splenomegaly, elevated basal metabolic rates and elevated blood uric acid levels. The duration of primary polycythemia varies between ten and fifteen years. Secondary polycythemia is a condition in which the peripheral red cell level is elevated usually in an attempt to overcome anoxemia. The duration of secondary polycythemia is determined by the process to which the polycythemia is secondary. Familial polycythemia is a congenital disease characterized by numerous small red blood cells but normal hemoglobin levels, normal rates of basal metabolism and normal blood uric acid levels. Familial polycythemia is not incompatible with a normal human life span. Radiophosphorus effectively inhibits mitosis of normoblasts in cases of primary polycythemia but not of secondary polycythemia. Thirty cases of primary polycythemia are reported that to date had 41 satisfactory remissions following the use of radiophosphorus. One patient with secondary polycythemia did not respond to radiophosphorus, as was expected. Radiophosphorus is the treatment of choice for primary polycythemia at present.

Nutritional Amblyopia in Liberated Prisoners.—Bloom and his associates present the clinical picture of American soldiers liberated after an extended confinement in Japanese prison camps under conditions of severe malnutrition. The study was done on 33 soldiers captured in April and May 1942 on Bataan and Corregidor and liberated in early 1945. The development of early symptoms was observed by one of the authors while a prisoner. The residual findings were observed by the other two collaborators while the patients were hospitalized in an army eye center in the United States. During the period from liberation to arrival at this eye center the patients had received an adequate diet and supplemental vitamin therapy and had returned to approximately their normal weight. Malnutrition due to a deficient diet can cause an optic atrophy manifested by defective vision, scotomas and pallor of the nerve head. The deficiency seems to be due to a lack of vitamin B_1, since the diet was highly deficient in this vitamin. The symptoms occurred coincidentally with beriberi and were relieved by thiamine when administered in the early stages of the deficiency. If treatment is not instituted early enough the condition becomes irreversible, as witnessed by the lack of improvement after administration of intensive vitamin therapy at the army eye center in the United States. Peripheral neuritis and optic atrophy were the only residual abnormal findings made at the eye center on patients who had suffered severe malnutrition over a period of years.

Tuberculosis as Occupational Hazard During Medical Training.—According to Morris a potential hazard exists when medical students are intimately exposed at their most vulnerable age to tuberculous patients and materials. The influence of sex on the prevalence of tuberculosis is still controversial. Data to the present support the claim of an earlier onset and earlier peak of mortality in women than in men. As comparisons of male medical students with students of nursing are misleading because their average age and duties are not comparable, it has been thought wise to report the experience at the woman's medical school while developing a program for the study of tuberculosis in women medical students. The survey covered the period from 1932 to 1944. A total of 449 students were observed. Fifty-six cases of the disease have been analyzed. Disease occurs earlier and progresses more rapidly in women than in men. Necropsy service and the use of tuberculous patients in demonstrations for physical diagnosis and clinical training constitute the chief sources of infection. When withdrawal of diseased students is delayed or students return before full stabilization, disease progression, relapse and spread to others may be expected. An adequate control program against tuberculosis in medical schools and hospitals is imperative. This should include case finding and follow-up programs in medical schools, establishment of safer technic in necropsy rooms, laboratories, clinics and wards of hospitals, obligatory entrance and periodic examinations of interns and residents, early care of all tuberculous patients and routine examinations of all college and hospital personnel, including ambulatory and bed patients

Tuberculin Reactors—Dash and his associates state that tuberculin testing for diagnostic case finding surveys has proved itself reliable by intracutaneous (Mantoux—with proper amount of tuberculin) and transcutaneous technics (Corper) A tuberculin test should be employed diagnostically in the event that finding surveys should reveal as close to 100 per cent as possible the number of cases of active tuberculosis verifiable by clinical and other diagnostic means, the test should give a minimum of tuberculin reactors among persons without tuberculous disease, the test should be easy to administer, it should cause minimum discomfort it should be readily interpretable and give reliable results and it should be of minimum cost and duration Most of the confusion relating to the number of reactors desired in a tuberculin test has been occasioned by a misunderstanding of the use to which such a test is to be put An entirely different problem exists in the use of a tuberculin test for purposes of screening persons who may have a tuberculous infection but do not have any verifiable tuberculous disease Such a tuberculin test must meet two conditions It should detect to a high degree specific tuberculoallergic individuals, and it should give a minimum of nonspecific reactions

Peroral Endoscopy L H Clerf, J R Fox and J A Fields —p 337

Neurinoma of Facial Nerve.—According to Kettel, neurinomas arise from the cells of the sheath of Schwann and are composed partly of Schwann cells and partly of connective tissue but do not contain true neural tissue The author reports a case in which a neurinoma somewhat larger than a hazelnut was removed from the pars descendens of the facial nerve of a woman aged 32 The clinical picture differed from that outlined in earlier reported cases The paralysis need not remain complete but may disappear, to recur later on The paralysis may persist for years without the tumors being visible in the acoustic meatus Severe pain may be present almost constantly for years

Concussion Deafness—Stewart and Barrow studied, with the aid of an audiometer and by whispered and spoken voice, 100 gunnery instructors assigned to both shotgun and 0 50 caliber machine gun ranges Each of them had normal hearing prior to assignment The length of service varied between six weeks and thirty months and the average was ten months On the ranges firing is almost continuous for seven and one half hours a day The noise level on ranges where forty or more 0 50 caliber machine guns are firing is high Men involuntarily duck, clasp their hands over their ears and have an almost uncontrollable impulse to run away when they first go on the range It is as if they were struck a physical blow by a mass of sound, but they soon become adjusted to the noise The noise of gunfire produces loss of hearing beginning in the high tones (2 048 to 11 584 cycles per second) among gunnery instructors When severe all tones are affected There was wide variation in individual susceptibility The average loss of hearing for both ears was 20 decibels The length of exposure necessary to produce damage varies widely from person to person After ten to twelve months of service on the range, further deterioration occurred slowly if at all Tinnitus was a complaint in 50 per cent of the men and was the most annoying symptom Since damage occurs insidiously and since damage to the conversational range is late few persons appreciate their handicap until it is far advanced Cotton plugs in the external auditory canal have not been effective in preventing loss of hearing There has not been significant improvement six months after cessation of exposure, and it is believed that the loss of hearing will be permanent

Primary Hyperparathyroidism—Norris studied the cases of parathyroid adenoma collected at the Army Institute of Pathology, 5 of which exemplify many typical characteristics and a number of important special features of primary hyperparathyroidism In these 5 cases the tumor was single and of moderate size In 3 the adenoma was associated with hypercalcemia, hypophosphatemia and the skeletal changes of osteitis fibrosa cystica generalisata, in 2 of these 3 cases there were manifestations of renal calcifications and lithiasis In 1 case, in which a severe state of hypoparathyroidism (hypocalcemia and convulsions) had been present at first clinical observation, there was nearly complete infarction of the parathyroid adenoma In 1 case the tumor was a true oxyphil adenoma This is a rare neoplasm It was not associated with skeletal or renal lesions Although more than 300 cases of adenoma of the parathyroid glands have been reported, knowledge of primary hyperparathyroidism is still incomplete It provides a favorable situation for analyzing the function of the different kinds of parathyroid cells in an effort to correlate their histologic structure and chemical activity Such study promises an advance toward understanding the normal physiologic and metabolic functions of these cell types

Stilbamidine in Multiple Myeloma.—Since the globulin content of the serum is also frequently increased in multiple myeloma, Snapper has tried stilbamidine for the treatment of multiple myeloma. In the beginning the myeloma patients were treated with fifteen injections of 150 mg. of stilbamidine given daily or every other day. More recently they have continued the treatment over a longer period and increased the total dose of stilbamidine to 5 or 6 Gm. Stilbamidine seems to have a specific influence on the severe bone pain which is so frequently a symptom of multiple myeloma. Often after the fourth injection, sometimes later in the treatment, the pain disappears. In 9 out of 14 patients an arrest of the progress of the disease has been realized. Two patients who were complete invalids before treatment have resumed their normal activities for sixteen months. The disease is arrested but not cured; the bone marrow of these patients still contains considerable numbers of myeloma cells. Favorable results have been obtained only in patients who followed a diet poor in animal protein. Animal protein evidently blocks the action of the drug, as is indicated by the negative results of the stilbamidine treatment obtained in myeloma patients fed on a diet rich in animal protein. Apart from this clinical improvement, stilbamidine causes morphologic changes in the myeloma cells. Large basophilic granules containing ribose nucleic acid appear in the cytoplasm which have a tendency to become confluent. None of the other bone marrow elements show comparable granules or inclusions.

Malignant Hypertension.—Selye and Stone state that constriction of the aorta in rats by means of a ligature between the origins of the two renal arteries may be gaged so as to inhibit urine formation completely in the kidney whose artery originates caudad to the ligature. The tubular epitheliums of such kidneys show no signs of degeneration or necrosis, although the nephronic lumens disappear and the organ assumes the appearance of an endocrine gland. Such "endocrine kidneys" continue to elaborate humoral substances which elicit changes characteristic of hypertensive disease in the remaining cardiovascular system. This shows that the formation of urine by a kidney is not a necessary prerequisite for its endocrine activity. The compensatory hypertrophy normally elicited by unilateral nephrectomy is inhibited by a purely "endocrine kidney" on the other side. Hence the growth of renal tissue must be partly regulated by renal humoral agents. The "endocrine kidney" is still responsive to the renotrophic effect of pituitary extracts. Under their influence, numerous mitotic divisions appear in the tubular epitheliums, and the weight of the organ increases. Partial constriction of the renal artery protects the kidney against nephrosclerosis. This protection is effective against humoral substances formed by this kidney and against the nephrosclerosis produced by anterior pituitary preparations. From this it is concluded that increased intravascular pressure is essential for the production of nephrosclerosis, since the humoral substances (renal and hypophysial) sufficient to produce lesions in the normal kidney do not cause nephrosclerosis in the "clamped" kidney of the same animal. Periarteritis nodosa and a special type of myocarditis (similar to that seen in acute rheumatic fever) can be produced by adrenal hypophysial and by renal hormones.

Anemia in Scurvy.—Wade and his associates report 4 cases of anemia and clinical evidence of malaria. The anemia improved under ascorbic acid therapy in each instance. Chronic vitamin C deficiency alone, or in combination with other deficiencies such as iron or the erythrocyte maturing factor, may produce anemia which will not respond optimally until adequate ascorbic acid therapy has been instituted. In the presence of scurvy it is probably unnecessary to resort to iron or liver until one has observed the hematologic response to ascorbic acid.

Electric Sleep (Shock) Treatment.—Holbrook says that during the past five years electric sleep or shock therapy has been used in 3,070 patients at several hospitals for mental diseases in New Orleans. A total of 27,231 treatments were given without fatality and with relatively few dislocations and fractures. Electric sleep therapy has so many advantages over insulin and metrazol that it has almost completely replaced these forms of treatment. While electric sleep therapy is used to treat dementia precox and hysteria, it is of paramount value in involutional melancholia, reactive depressions, the depressions which are part of the manic-depressive syndrome, and other emotional disorders. It is used in treatment of the excited phase of manic-depressive syndrome but the results are not so brilliant. All depressions should receive this form of therapy even when the psychosis is of several years' duration. In schizophrenia better results are obtained through electric sleep treatment than by any other method, but in certain cases of schizophrenia insulin is superior to electric sleep treatment. The electric treatment is also valuable in maintaining certain chronic cases at a higher social adjustment than could be otherwise obtained.

External Use of Radioactive Phosphorus.—According to Low-Beer the physical properties of radioactive phosphorus (P^{32}) make it suitable for studying the effect of beta particle radiation on the skin. The radioactive phosphorus was an aqueous solution of disodium hydrogen phosphate containing 15 mg. of the salt per cubic centimeter of water. Ordinary thin blotting paper was the most suitable vehicle for the radioactive solution. The intensity of the erythema depends on the amount of exposure. The depth of discernible biologic effect from externally applied radioactive phosphorus was approximately 5 mm. for erythema-producing doses. "Threshold erythema" was produced by an exposure to 34 microcurie hours per square centimeter. Results suggest that radioactive phosphorus might be used in local treatment of certain superficial skin diseases.

Chest Surveys in Dachau Concentration Camp.—Piatt presents a statistical compilation of the roentgen findings in the initial roentgenograms of 2,267 patients in the Dachau concentration camp. Active tuberculosis was demonstrated by x-ray in 626 (27.54 per cent). It is assumed that a large number of the 365 cases of undiagnosed pneumonic densities, peribronchial infiltrations (pneumonitis), pleural effusions and pneumothoraces were of tuberculous causation. The heart shadow of 269 persons (11.8 per cent) was enlarged. A surprising number of enlarged hearts were found in persons with moderately and far advanced tuberculosis, although by far the larger number of cardiac shadows in tuberculous patients were quite small. The prominent hearts in the nontuberculous and tuberculous cases probably represent a hypertrophy or transient dilatation due to an avitaminosis.

Primary Atypical Pneumonia.—McCoy reports 420 cases of atypical pneumonia observed at the Station Hospital, Camp Rucker, Alabama. One fatal case appeared to be a primary interstitial pneumonitis which became secondarily complicated, resulting in bronchopneumonia and other chest findings. Associated anatomic findings were cloudy swelling of the liver, kidneys and adrenals, acute splenic tumor and testicular atrophy. The diagnosis of atypical pneumonia is based on clinical observation. Significant diagnostic points include roentgen changes with minimal physical findings, negative sputum, relatively normal leukocyte count, low pulse rate and failure to respond to sulfonamides. There was no appreciable correlation between the incidence of common respiratory infections and atypical pneumonia. Despite the minimal physical findings as compared with roentgen evidence of pulmonary involvement, daily examination of the chest during the acute phase of illness in atypical pneumonia showed some physical findings in 94.25 per cent of the cases studied. Complications, unusually mild in this group, included extension of the pneumonic process, pleural involvement and delayed resolution. The treatment of atypical pneumonia is symptomatic. Sulfonamides are valueless; oxygen and transfusions are helpful for the more severely ill patients. Penicillin deserves further evaluation in the treatment of complicated cases.

Spinal Fluid Protein in Subclinical Poliomyelitis.—Andelman and his associates studied contacts, noncontacts and controls of poliomyelitis patients. Spinal fluid examinations were made ten to sixty days after the onset of fever among contacts, noncontacts and controls. One hundred and forty-two spinal fluid examinations were analyzed on 43 contacts who within five to twenty-one days after the exposure developed illness which was either outright poliomyelitis or mild fevers suspected of being this disease and on 45 noncontacts and controls who developed febrile illnesses which were not believed to have been poliomyelitis; also on 39 patients with paralytic and 15 with meningitic forms of the disease. The spinal fluid protein level was above 45 mg in 15 of 19 contact children suspected of convalescing from subclinical poliomyelitis These were examined eleven to forty-five days after the onset of the illness, the spinal fluid being within normal limits in each instance and averaging 27 3 mg Only 10 per cent of 43 control children having acute illnesses other than those primarily affecting the central nervous system had spinal fluid protein elevated above 45 mg, although the general level was significantly raised to 33 mg A base line of 27 mg was found for recovered poliomyelitic patients some fifty to sixty days after onset The increase in the spinal fluid protein in subclinical poliomyelitis confirms the accuracy of the spinal fluid protein as an indicator The 20 to 25 per cent of contact children suspected of convalescing from subclinical poliomyelitis but who had no increase in spinal fluid eleven to forty-five days after onset may nearly all have been suffering from the disease since 20 to 25 per cent of known paralytic cases likewise exhibited normal spinal fluid protein levels during the same period Although the determination of spinal fluid protein levels was recommended or proposed by early workers as a means of detecting nonparalytic poliomyelitis in the convalescent period, this study is first to report its application in a systematic field study The consistent and prolonged rise of the spinal fluid protein level in subclinical poliomyelitis (equal to that in the paralytic form) indicates that this form of the disease is not 'mild," that it is possibly accompanied with lesions of the central nervous system and that it is sufficient to give rise to a lasting immunity.

Clinical Manifestations of Local Shock.—According to Thomson, local shock is a clinical sequence of pathologic changes exhibited after severe injuries (particularly crushing) of the extremities characterized by local vasospasm Acting first as a safety reflex to stop hemorrhage and additional trauma, it may result later in capillary dilatation incompetence or decompensation thereby (1) preventing normal tissue metabolism, (2) interfering with the normal interchange of tissue fluids in the region of injury with loss of plasma, (3) piling up the products of trauma, with no effort being displayed toward their evacuation and (4) ending often in degeneration and local death of the tissue From observations on more than 300 rabbits the author concludes that procaine block of the sympathetics controlling a severely injured extremity tends to restore circulatory integrity and equilibrium Stopping vasoconstriction also stimulates capillary competence and the interchange of tissue fluids, organization of a clot the appearance of fibroblasts proliferation of capillaries calcification of necrotic muscle tissue and an early healing process The author does a sympathetic procaine block almost routinely on all severe injuries of the extremities He presents 4 striking examples of a series of 48 cases in which he had experience with stellate and lumbar sympathetic block

Dysgerminoma of Ovary—A girl aged 12 years presented symptoms that led to the diagnosis of a left ovarian cyst Microscopic examination of the surgical specimen disclosed dysgerminoma The child was free from recurrence or metastasis eighteen months later Custer stresses that early diagnosis and operation is the only hope for these patients He is convinced that dysgerminomas are malignant tumors, since all patients who showed extension at the time of operation died of metastases

Tetraethylammonium in Peripheral Vascular Disease and Causalgic States.—Berry and his associates direct attention to the new method of producing a blockage of autonomic ganglions by parenteral injection of the tetraethylammonium ion Tetraethylammonium was injected intravenously or intramuscularly in a 10 per cent solution The intravenous dose ranged from a minimum of 100 mg (1 cc) to a maximum of 500 mg (5 cc) This was injected slowly over fifteen to sixty seconds Intramuscular injections were utilized to prolong the effect of the autonomic blockade only in patients under observation in the hospital These were given in doses less than 20 mg per kilogram of body weight 1 to 1 5 Gm, one-half the dose administered in each buttock Approximately 500 patients have received tetraethylammonium bromide or chloride on one or more occasions either as a diagnostic or as a therapeutic measure or both These patients fall into two general groups, patients with hypertension and patients with peripheral vascular disease and allied disorders The latter group included patients with peripheral arteriosclerosis obliterans, thromboangiitis obliterans, functional vascular disorders including Raynaud s syndrome, livedo reticularis, acrocyanosis and other unclassified vasomotor disorders, causalgias including various types of reflex sympathetic dystrophy, superficial and deep thrombophlebitis, various types of lymphedema post-traumatic edema, scleroderma, endarteritis herpes zoster and postherpetic neuralgias, trench and immersion foot sequelae and a nondescript group of widely varying nature Many of these patients received courses of therapy extending over a period of several days Others received only a single *injection* usually intravenously, or were given periodic weekly or *monthly* injections to produce a sympathetic block as the need arose The drug has proved satisfactory

Lesions in Muscle in Arthritis.—Perivascular cellular reactions in the muscles themselves and paravascular lesions in the fibrous and fatty supporting connective tissue were observed by Gibson and his associates in specimens of biopsy material taken from 11 patients with typical rheumatoid arthritis in 10 and with some atypical features in 1 There were 5 men between the ages of 48 and 63 and 6 women between the ages of 33 and 52 Similar changes were found in active and quiescent cases, whether or not they had been treated with gold salts All affected tissues were of mesodermal origin. It is suggested that the noxious agent is a blood borne irritant

Virus Receptor Gradient in Red Cells.—Burnet and his associates define a "receptor gradient" in human erythrocytes for viruses of the mumps-influenza group Cells which have been treated by influenza viruses in addition to losing their agglutinability by some or all of the viruses of the group develop a susceptibility to serum agglutination analogous to the "panagglutinability" described by Thomsen Virus receptors can be removed in almost the order of the receptor gradient by enzymes produced by Clostridium welchi and Vibrio cholerae. The ability of two different types of bacterial products to change the surface character of human red cells so that they become progressively less sensitive to agglutination by viruses is a function of one or more enzymes in the material The possibility that lecithinases are concerned is suggested by the fact that active enzymes of this character are produced by both Cl welchi and the cholera vibrio Two differences in the activity of bacterial enzymes on the one hand and the action of influenza viruses on the other have been observed: 1. Mumps virus receptors are more readily removed by virus action than by vibrio filtrates, and there is a less evident but probably significant difference in the same direction with Newcastle disease virus receptors 2 With vibrio filtrates removal of virus receptors may be almost complete, with little development of serum agglutinability by the cells Unfiltered cultures have usually produced both effects, while older cultures have rendered the cells permanently unstable and therefore unsuitable for testing Should it develop that similar enzymes are an intrinsic part of viruses of the mumps-influenza group, two important possibilities arise: (1) that these enzymes play an essential part in the initial invasion of susceptible cells as well as in adsorption to erythrocytes and (2) that the nature of the enzymes may open up an opportunity for chemotherapeutic studies

Agglutination of Red Cells by Mononucleosis Serums.—Burnet and Anderson show that the virus of Newcastle disease of fowls agglutinates human cells and is eluted therefrom in the same fashion as influenza viruses. Cells treated with amniotic or allantoic fluid preparations of Newcastle disease virus develop a new antigenic character which allows them to be agglutinated to high titer either by experimental Newcastle disease virus immune serum or by most serums from recent cases of infectious mononucleosis in man The changed character of the cells is due to the adsorption to their surface of an agent other than the virus produced during the growth of Newcastle disease virus in chick embryo cells The possible significance of this agglutination reaction as a lead to the etiology of infectious mononucleosis is discussed

Agglutination Test for Mumps Antibody.—Burnet demonstrates that human erythrocytes treated with mumps virus are *specifically* agglutinated by mumps antibody. The reaction can be used as a sensitive quantitative test for antibody in human serum

Relationship Between Primary and Adult Pulmonary Tuberculosis S R. Gloyne —p 93

*Detection of Tubercle Bacilli by Fluorescence Technic. J W Clegg and A F Foster Carter —p 98

Relationship Between Primary and Adult Tuberculosis.—Ustvedt asserts that the great majority of primary tuberculous infections now take place in the same age groups in which the largest percentage of destructive pulmonary tuberculosis is found The time interval is in most cases less than five years, often only one or two years Primary tuberculosis apparently is sometimes very malignant Destructive pulmonary tuberculosis begins in many cases with a new infiltration which seems to have a metastatic origin The most important practical consequence of this view is that demonstration of the primary infection by tuberculin tests is of decisive importance and that the infection must be carefully watched, particularly in the first few years after it has been contracted.

Detection of Tubercle Bacilli by Fluorescence Technic.—Clegg and Foster-Carter describe an apparatus for the routine examination of pathologic fluids for tubercle bacilli by the fluorescence method. They found the fluorescence method just as accurate, more sensitive and more rapid than the Ziehl-Neelsen technic. They recommend the fluorescence technic to any laboratory where large numbers of examinations for tubercle bacilli are done.

Tongue Changes in British Troops.—Smith directs attention to a symptomless tongue condition which was occurring among British troops in India and southeastern Asia commands and which was giving rise to diagnostic difficulties. The principal features of this condition were fissuring, epithelial changes and changes in the architecture of the papillae. The most probable cause was considered to be a nutritional deficiency, probably of riboflavin. However, improvement did not follow treatment with thiamine, riboflavin and niacin; that is, evidence is against the tongue changes being of nutritional origin. The chief object in publishing this paper is to draw attention to the frequency of tongue changes, which are apt to be diagnosed as due to deficiency disease and to enjoin caution in their acceptance as such.

Addison's Disease Successfully Treated by a Graft.—Broster and Gardiner-Hill present the story of a young woman in whom, nine months previous to their seeeing her, a diagnosis of Addison's disease had been made. The authors confirmed this diagnosis, and one of them ingrafted an adrenal gland from a patient with the adrenogenital syndrome (hyperplasia). As a result of this operation the young woman lost her symptoms and signs of Addison's disease, and sodium chloride withdrawal tests showed that her blood sodium no longer fell below normal. The last test (fourteen months after operation) showed that this change had been maintained.

Asthma and Urticaria Following a Bee Sting.—Reed reports that a European aged 31, within three minutes after being stung by a bee on the left ear, developed a flushed face, throbbing of the head and swelling of the nasal mucosa. A minute or so later he began to wheeze, and an attack of asthma developed. Epinephrine gave relief from the asthma, but urticaria appeared over the entire body. More epinephrine was injected, and ephedrine was given in tablet form. While the epinephrine and ephedrine controlled the asthma and urticaria, they did not affect the erythema, but this and the irritation cleared in forty-eight hours.

Value of Butter Fats and Vegetable Fats for Growth.—Basu and Nath found that butter fat when fed to young rats at 3, 6 and 9 per cent levels induced maximum growth at the 6 per cent level. The growth was poor at the 3 per cent level. Comparative tests were then made with mustard, coconut, sesame and peanut oils and with cow or buffalo butter fats, all given at the 6 per cent level. Maximum growth was obtained with cow butter fat. The growth with buffalo butter fat was slightly less. The vegetable oils gave less growth.

Uses of Plastics in Surgery. G. Blaine.—p. 525.

Psychoneuroses Treated with Electrical Convulsions.—Milligan describes the treatment of 100 psychoneurotic patients with electric convulsions. The average dose used has been 180 volts at 0.4 second. This produces a convulsion in nearly every case and has the advantage that it eliminates the usual preceding cry, which is helpful when many patients are being treated in a ward. The only precaution taken, apart from the gauze gag, is the use of a dorsal pillow to keep the patient in a position of slight opisthotonos. Radio music helps patients awaiting treatment to pass the time and prevents apprehension. The authors have used an intensive method in many cases, which sometimes involves four treatments a day. Some patients are reduced to the infantile level and then allowed gradually to emerge from the confusional state. During this time simple psychotherapy is given. Occupational therapy is used as an adjuvant. After discharge the patient usually returns to work immediately and reports at the outpatient department for several months. All patients responded well.

Penicillin in Treatment of Yaws.—Hill and his associates report observations on 128 patients with yaws (15 primary, 96 secondary and 17 tertiary) treated with penicillin. The patients were all African children or mothers. The most advantageous method of treatment was a daily injection of 100,000 Oxford units in peanut oil and beeswax up to a total dosage of at least 1,000,000 units. Spirochetes disappeared from the lesions in from nine to twenty-four hours after doses of 50,000 to 200,000 units. There was remarkably rapid healing of the acute lesion in primary and secondary yaws, the average time being nine days. Considerable success was achieved with bony lesions of tertiary yaws. No correspondence could be found in the follow-up investigations between sustained clinical cure and reversal of the Kahn reaction. Twenty patients were given penicillin with either acetylarsol or neoarsphenamine. The results suggest that penicillin followed by a more prolonged arsenical treatment is the ideal therapy for ultimate and permanent cure.

Estrogens in Carcinoma of Prostate.—Fergusson carried out repeated biopsies of the carcinomatous prostate and of accessible metastases in order to ascertain the results of estrogen therapy. The neoplasm regressed during treatment in nearly all of 9 cited cases, as was indicated both by microscopy and, in 4 of the cases, by tissue acid phosphatase estimation. However, some cases of prostatic carcinoma do not seem to respond to estrogens. There is some evidence that estrogens are effective against metastases. Investigations carried out to ascertain whether the presence of acid phosphatase in lymph node metastases is pathognomonic of prostatic carcinoma revealed that much acid phosphatase in a lymph node suggests, but does not prove, a primary prostatic cancer, for it was found also in lymph nodes involved by carcinoma of the stomach or of the penis and in some tuberculous lymph nodes. The average survival periods of 23 patients treated with estrogens were longer than those of 27 patients not so treated.

Diagnosis of Schistosomiasis.—Alves and Blair describe the preparation and use of cercarial antigens for intradermal testing in suspected cases of schistosomiasis. A higher proportion of cases of schistosomiasis is revealed by this antigen than can be detected even by repeated microscopic examinations. This skin test is of value also in ascertaining the efficacy of a treatment. Since no negative skin reactors have been found to be passing eggs, the test can be used as a rapid and accurate "screen" in mass treatment campaigns. Its use in indicating the need for further treatment is also outlined.

*Estimation of Prostatic Phosphatase in Serum and Its Use in Diagnosis of Prostatic Carcinoma. Freda K. Herbert.—p. 221.

Estimation of Prostatic Phosphatase in Serum.—Herbert made a study of the diagnostic use of estimations of serum acid phosphate on the basis of 87 cases of prostatic carcinoma, 95 cases of prostatic hypertrophy and 153 cases including a wide variety of diseases. The total acid phosphatase titer is raised in the great majority of cases of prostatic carcinoma with metastases in bone and in a small proportion of cases without demonstrable bone metastases. In order to assist diagnosis in cases in which the serum acid phosphatase is only slightly raised, methods of inactivation of prostatic phosphatase have been studied. The incubation of the serum at 37 C. is not recommended as a routine diagnostic test, but inactivation by alcohol at room temperature gives a specific test for prostatic phosphatase and an approximately quantitative measure of the prostatic fraction of the acid phosphatase.

*Latent Tuberculosis of Female Genital Organs: Its Frequency and Importance as Cause of Sterility in Women. I. Halbrecht.—p. 708.

Latent Tuberculosis of Female Genital Organs as Cause of Sterility.—Halbrecht says that of 820 sterile women who were subjected to curettage 45, or 5.5 per cent, were found to have a tuberculous endometritis. Among 54 women with partial or total occlusion of the tubes there were 18, that is, a third, who had tuberculous endometritis. He concludes from these observations that latent genital tuberculosis seems to be rather frequent in apparently healthy women, but particularly in sterile women. This form of genital tuberculosis remains stationary for a long time or permanently, but it nearly always terminates in obliteration of the tubes and thus renders these women sterile. The tuberculous nature of the condition is usually discovered accidentally by a curettage. It is advisable to abstain from surgical treatment in cases of this type, since even curettage may cause serious complications.

*Bite of the Flax Spider. V. Grille Cendan.—p. 603.

Bite of the Flax Spider.—During the harvest of flax in summer the bite of the flax spider is frequent in rural zones of Uruguay. Grille Cendan observed 6 patients. As a rule the spider attacks when the workers are taking their siesta under a tree. The bite causes acute local pain, which immediately involves the entire extremity and the lymphatic system. The clinical symptoms are mainly motor, with very painful tetanic contractures of striated muscles. Bites on the thoracic muscles cause disturbances of respiration. Opisthotonos and trismus frequently occur. Fever and diminished urination also occur. The symptoms are so characteristic as to make the diagnosis obvious even if the spider has disappeared. The treatment consists in administration of morphine, rest in a quiet dark place, repeated hot baths of twenty minutes' duration, a purgative enema on the second day of the attack and administration of chloral in daily doses of 6 Gm. The treatment is continued for a week or ten days up to recovery.

*Ambulatory Oral Penicillin Therapy in Gonorrhea in Children. A. Wiederhold and Antonieta Méndez.—p. 367.

Penicillin Therapy in Gonorrhea in Children.—Penicillin was given orally to 26 infants and children with subacute gonorrheal urethritis in boys or subacute vulvovaginitis in very young girls. Duration of the disease varied from five days to three years. Sulfonamide had been given to the majority of the patients without effect. Penicillin was administered by mouth three times daily in doses of 33,000 and 100,000 units every four hours for three consecutive days up to a total dose of 300,000 to 900,000 units. A total dose of 1,500,000 units was given in the course of three consecutive days only in 1 case of acute vulvovaginitis. All patients were clinically and bacteriologically cured. The patients were observed for six months after completion of the treatment. Reactivation tests after either instillation of a 10 per cent solution of strong protein silver or a hypodermic injection of ergotamine tartrate were carried out at intervals during this period. Permanent cure was verified in the majority of cases by absence of gonococci in smears and cultures of urethral and vaginal secretions. In a few cases gonococci reappeared after reactivation tests but disappeared later either spontaneously or after repetition of penicillin therapy.

*Intraocular Injections of Penicillin. J. A. van Heuven.—p. 1006.

Camp Vertigo.—Kuilman applies the term camp vertigo to a type of dizziness that was observed among prisoners of war in the Far East. At a hospital for prisoners of war in Batavia, Java, during 1944 and 1945, complaints of dizziness were made by 563 patients, and in 412 of these the diagnosis of camp vertigo was made. This form of vertigo is not to be regarded as a labyrinthine disturbance but is considered the result of a central disturbance of the supranuclear mechanism controlling the synergic movements of the eye. It is thought that the condition is due to avitaminosis. The patients probably had a deficiency of one or more factors of the vitamin B complex. A large number of the patients with this type of dizziness responded favorably to treatment with yeast. A form of bilateral deafness, which was probably also the result of some deficiency, was observed in 43 prisoners of war. In 37 of these 43 patients the camp deafness was combined with vertigo.

Intraocular Injections of Penicillin.—Van Heuven used 2 cc. of penicillin solution (10,000 units per cubic centimeter) for the irrigation of the anterior chamber of the eye. One of the patients, aged 74, had undergone an operation for cataract, which was followed by infection and panophthalmia. The second patient, aged 19, had been hit in the eye with a tennis ball. This patient had developed an ulcer at the margin of the cornea and sclera and a hypopyon. In both patients irrigation with solution of penicillin was followed by disappearance of the hypopyon. In the second patient the irrigation of the anterior chamber was repeated after five days. This was followed by great improvement.

Uterine Changes in Besnier-Boeck-Schaumann's Disease.—Engelhard observed 2 women with uterine involvement in Besnier-Boeck-Schaumann's disease (Boeck's sarcoid). The first patient was a woman aged 64 who had not menstruated for twelve years. She complained of a uterine discharge, but examination revealed a normal cervix and normal adnexa. Tissue obtained on curettage contained giant cells. A roentgenogram of the thorax disclosed an enlarged hilus lymph node. The hands and feet showed sarcoid lesions, and round areas of lesser density were observed in the legs. On the basis of the urinary changes, diabetic treatment was instituted and the urine became normal. The uterine discharge ceased and the genitalia were normal, but roentgenoscopy still disclosed the same changes. The second patient also had uterine and cervical changes characteristic of Boeck's sarcoid. The author says that, while the literature contains reports of tuberculosis of the cervix and uterine mucosa, he did not find any records of uterine involvement in Besnier-Boeck-Schaumann's disease.

Transparency of Corneal Tissue. T. Caspersson and A. Engström.—p. 1279.

Cholesterol Deposition and Atheromatosis.—Cholesterol depositions are characterized by extracellular beginning. The most important are those in the aorta and other central vessels in atheromatosis. Two factors in the development of the deposits are (1) the influence of the amount of cholesterol supplied by the blood stream and (2) a tissue factor responsible for their localization. The tissue factor seems to dominate in arcus lipoides, in the concentration of the serum cholesterol and in xanthoma palpebrarum. In atheromatosis of the central vessels cholesterol has a decisive influence, particularly when hypercholesteremia is demonstrated. In hypercholesteremia an acceleration of cholesterol deposition takes place. Increased serum cholesterol predisposes to an earlier atheromatosis. An injury with following reparative processes promotes cholesterol deposition in the aorta. Hypertension seems to act through a tissue factor. Cholesterol in the aorta is found at the site of metachromatic substance. Metachromasis is present where cholesterol is normally found and also in pathologic cholesterol deposits in chronic salpingitis, cholesterol pleurisy and Schüller-Christian's disease. The three known metachromatic substances in the organism, chondroitin, mucoitin sulfuric acid and heparin, seem to be equally active. The mechanism in cholesterol deposition is still unknown.

Book Notices

The Psychoanalytic Theory of Neurosis. By Otto Fenichel, M.D. Cloth Price, $7.50. Pp. 703. W. W. Norton & Company, Inc., 70 Fifth Ave., New York 11, 1945.

This book represents the completion of a difficult task. In order to explain the psychoanalytic theory of neurosis, the author has found it necessary to detail the mechanics of the entire range of mental phenomena, from the growth and development of the normal personality to every phase of mental illness. The book is not intentionally descriptive and thus presupposes a familiarity on the part of the reader with psychiatric syndromes. The author's interest is confined to an elucidation of the mechanics underlying normal and abnormal behavior. In part I, on preliminary considerations, a short introduction regarding the general nature of freudian concepts leads to a long and extremely lucid statement on the development of the mental apparatus and the personality. The description of the extraordinarily complex mechanisms involved in this development is deftly handled. The author repeatedly stresses the obvious gaps and deficiencies in our present day knowledge, especially of psychologic-physiologic correlations. In spite of the difficulties resulting from ignorance of exact and measurable data, the theory of the development of psychologic mechanisms in the infant, child and adolescent compels recognition because of its usefulness in understanding the psychologic problems of adults.

In part II Fenichel undertakes the application of this theory of the development of the personality to the symptoms of clinical illness and of abnormal behavior. The core of neurosis is represented as the "neurotic conflict," the central task of the ego as the avoidance or solution of such a conflict. To demonstrate the origin of a neurotic conflict the author begins the exposition with the traumatic neuroses, in which the ego is overwhelmed by excitation due to external stimuli, and mastery or an adequate adaptive response to the situation is impossible. Psychoneurotic symptoms are conceived as secondary to the traumatic neuroses, resulting when the ego has failed to solve adequately its reaction to the original situation. Every psychoneurosis is thus the result of a "relative trauma." The individual symptoms of the psychoneurosis (or psychosis or psychopathy), although exceedingly complex and overdetermined, are in general the result of a regression of the ego, following its failure, to an earlier, more immature way of adapting to reality plus attempts to defend itself against or negate the consequences of such a regression. The conflict lies between the regressed part of the ego, committed to infantile modes of behavior, and the more mature ego responsive to culturally acceptable standards. The depth of the regression taken with the type of defense put up by the more mature and conscious part of the ego determines the type of neurosis which appears.

In filling in the details of this theory, Fenichel goes to exhaustive and almost superhuman lengths. Every clinically discernible type of psychiatric disorder is subjected to patient and scrupulous analysis in the light of regression, defense and neurotic conflict. For each clinical symptom a myriad of theoretically possible dynamic mechanisms is presented. The psychoanalytic and psychiatric literature is thoroughly combed lest some nuance of a dynamic interpretation escape mention, and the text is supplemented by a bibliography and index of gargantuan proportions. Although this method of proceeding by infinite and laborious detail makes the book superb as a source of psychoanalytic interpretations of symptoms, by the same token it loses considerable force as an exposition of psychoanalytic theory. The reader becomes entangled in the variety and subtleties of possible mechanisms and loses the main outlines of the theory. Furthermore, because what is described is always a symptom and its mechanism, the human characteristics of every neurotic problem are obscured by the somewhat mechanical approach.

Nevertheless the book rises above its defects. In spite of the considerable repetition and infinite detail, it remains a contribution of the greatest value to psychiatric literature. The encyclopedic task accomplished by Fenichel will prove rewarding both to the newcomer to psychoanalytic theory and to the practicing psychiatrist in search of source and reference material.

Diagnostic Psychological Testing: The Theory, Statistical Evaluation, and Diagnostic Application of a Battery of Tests. Volume II. By David Rapaport, Ph.D., with the collaboration of Merton Gill, M.D., and Roy Schafer, B.S. The Menninger Clinic Monograph Series No. 4. Cloth. Price $6.50. Pp. 516, with illustrations. Chicago: Year Book Publishers, Inc., 1946.

This volume by members of the research staff of the Menninger Foundation deals with the so-called projective tests; volume I presented the authors' work with nonprojective tests, the Bellevue scale, the Babcock test and the sorting test. The present work covers studies with the word association test, the Rohrschacher test and the thematic apperception test. These are diagnostic tests of personality and ideational content in contrast to tests of intelligence and achievement. The first chapter discusses the nature, applications and misapplications of the projective tests. The chapter on the word association test presents the psychologic rationale of the test, the method of administration and the results of analysis of the stimulus words. The diagnostic significance of disturbances in the associations in the groups of psychotic and neurotic persons to whom the test was given are discussed. As a result of their analyses the authors have undertaken to revise the stimulus-word list both as to content and as to sequence. Their list contains only noun stimulus-words and is revised to touch on significant relationships and conflict areas.

The bulk of the work (310 pages) is devoted to the Rohrschacher test. The authors emphasize the fundamental simplicity of the test despite its apparent complexity. In this study the aim was to validate the significance of the different responses, to standardize the diagnostic use of the responses and "to systematize a manner of analyzing the verbalization of Rohrschacher responses, a task which has been thus far neglected in the main, to the detriment of the test's diagnostic potency." Method of administration, scoring, rationale and careful analyses of the responses of the several clinically distinct groups of psychotic and neurotic persons are exhaustively presented and discussed. A summarizing section gives the individual diagnostic findings on examination of 217 persons in the several groups referred to. The observations on a "normal" control group are briefly summarized and contrasted with those evidencing abnormalities clinically.

The thematic apperception test is one in which the subject is required to make up a story around a picture presented visually. This test is included to offer "an appraisal of the subject's experiencing of his own world and of himself as part of it." Content and attitudes revealed in such a test are only incidentally revealed in the word association and Rohrschacher tests. The presentation of material on this test follows the general plan of discussion of the preceding tests, with emphasis on technics of interpretation and diagnostic indications. A final chapter briefly discusses the problem of diagnosing with a battery of tests. Here a few important rules for use of a battery of tests are laid down, together with discussion of differential diagnosis, weighting of the various tests as diagnostic tools, limitations and broader possibilities of their usefulness. Appendixes provide tabulations of the Rohrschacher score of each subject and an extremely useful review of the literature of the tests used in the study.

This book is written primarily for the specialist in clinical psychologic testing but is of greatest importance and interest to all psychologists and psychiatrists. It offers much to the student and research worker. The consistent effort to determine what it is that happens psychologically within the subject when confronted with the necessity to respond to the test, the meticulousness of the analyses of the individual tests and a clinical perspective doubtless enhanced by the particular setting in which the studies were made conspire to produce an impressive and important work. Doubtless the Rohrschacher in particular will find much to shoot at in further effort to establish fully the usefulness, meaning and application of this amazing test.

Les phénomènes d'allergie non spécifique dans la tuberculose et les fièvres typhoïdes: Importance de la notion des phénomènes de Sanarelli-Schwartzmann, les limites de la spécificité pathogène, contribution à l'étude de la pathogénie de la tuberculose et des fièvres typhoïdes. Par Jean Albert-Weil. Préface du Professeur René Leriche. Paper. Pp. 83. Libairie Maloine, 27, rue de l'Ecole-de-Médecine, Paris, 6e, 1946.

This small monograph gives the various conceptions of the author on nonspecific allergy in tuberculosis specifically and is based on general conceptions of other authors. The presentation is divided into three main parts. The first reviews the phenomena of allergy in tuberculosis and of nonspecific allergy, sensitization and the toxic and allergic feature of the histopathologic tuberculosis, including the involvement of the neurovegetative system. The conceptions of Besredka and Ghon are given consideration. The specificity of the terrain is considered, and its effect on the virulence of the bacilli noted. The phenomenon of nonspecific tuberculin is discussed, and the role of the neurovegetative system in the reaction of hypersensitiveness expounded. The action of the tubercle bacillus on the tuberculous terrain is viewed in the light of the development of the virulence of other germs (colon bacillus and others). The second part considers the nonspecific allergy in typhoid-like fevers and the part played by the typhoid bacilli and their lesions on the multiplication and virulence of colon bacilli. The influence of tissue necrobiosis on the multiplication and virulence of bacteria is noted, and its importance in the role of the pathogenesis of morbid allergic and toxic phenomena, tissue sensitization to intestinal saprophytes during the course of typhoid, sensitization and autosensitization toward colon bacilli and associated activation of virulence, group sensitization and the involvement of the Sanarelli-Schwartzmann phenomena in the course of typhoid and paratyphoid are discussed. The third part considers the limits of bacterial specificity and the mosaic character of bacterial antigens. A brief conclusion summarizes the author's views and the possible relations to therapy on this basis.

Since this monograph is one of general conceptions and a personal point of view with which many might readily dissent as to its practical significance, especially in tuberculosis, it can only be suggested that the monograph be read by those interested in nonspecific allergies and their possible significance, so inherently one of points of view, in an involved field such as allergy.

If You Ask My Advice: Frank Discussions of Family Problems. By Henry Pleasants Jr., M.D. Cloth. Price, $2. Pp. 110. Bruce Humphries, Inc., 30 Winchester St., Boston, 1946.

Eight subjects ranging from family problems to insurance are discussed rather superficially. Although the manner of presentation is easy-going, with liberal use of homely phrases and emphasis on informality, conclusions that are definitely helpful are seldom reached. For example, in the essay titled "This Thing Called Sex" the author drops the subject of child education back in the parental lap with the casual query "Would it not be better to explain the whole problem of sex to youngsters in such a way that they can understand the simple basic reason back of the annoying restrictions?" The author is to be commended for keeping the matter of medical treatment on a superficial plane, but one might find fault with conclusions such as are presented in the case of a woman in whom sanity was restored . . . or at least her mind made "clear as crystal" . . . by correction of faulty intestinal elimination.

Zur Physio-Pathologie der Niere. Von Dozent Dr. med. Otto Spühler, Oberarzt der Med. Universitats-Poliklinik Zurich. Mit einem Vorwort von Prof. Dr. med. P. H. Rossier. Cloth. Price, 17.50 Swiss francs. Pp. 248, with 22 illustrations Bern: Hans Huber, 1946

The author's intention is threefold. He presents, first, a text in German ably summarizing the technics and concepts of modern renal physiology. Second, he seeks, albeit only at the sacrifice of clarity, to coordinate these with the older views on renal function. Third, and even less fortunately, he interpolates illustrative data from his own observations of inulin, urea, uric acid and chloride clearances. The principal topics are glomerular filtration, renal blood flow, tubular activity and diuresis. The author apparently is not familiar enough with the pitfalls of renal function testing to appraise his data critically. It is especially difficult to reconcile the average urea clearance of only 37 cc. per minute which he finds in normal subjects with the concurrent average inulin clearance, technically the more difficult procedure, which is correctly found to be 120 cc. per minute. The brief discussions of toxemia of pregnancy and hypertension are sketchy and might better have been omitted. Due allowance should be made for the fact that American and English journals in which most of the relevant articles of recent years have appeared seem to have been unobtainable in Switzerland after 1941. The book will direct European attention to the great strides in the study of renal function made in this country. As such it represents a laudable relaxation of continental complacency. It is well printed, indexed and bound and contains few typographic errors.

Cancer of the Scrotum in Relation to Occupation. By S. A. Henry, M.A., M.D., F.R.C.P. Oxford Medical Publications The Substance of This Paper Was Contained in the Hunterian Lecture Delivered at the Royal College of Surgeons on 2nd February 1940, but Information Which Has Since Become Available Has Been Added. Paper. Pp. 112, with 33 illustrations. New York, London & Toronto: Oxford University Press, 1946.

This is a laudable attempt to elucidate the causation of epithelioma of the scrotum. Much information is included on the causes of skin cancer and on carcinogenic substances. Detailed studies of the incidence of scrotal cancer in various occupations and industries are correlated with the probable carcinogenic agent in each. The author has used as material for study all cases (3,333) of notifiable epitheliomatous ulceration of the skin since 1920, and all fatal cases of scrotal cancer (1,638) in England and Wales from 1911 to 1938. This tumor causes only 0.25 per cent of all cancer deaths but, because of its rarity, its incidence in certain occupations becomes all the more revealing. There are discussions on the agents encountered, the time necessary for the production of the primary growth (induction time), the period of delay between the last exposure and manifestation of the disease, and other points. There are brief chapters on prevention and treatment and a historical introduction which begins with the observations of Percival Pott on chimney sweeps' cancer of the scrotum—the first known recorded example of the cause of a cancer. Excellent photographs are included, but the bibliography refers mainly to British papers and there is no broad critical review of the subject. The volume contains a wealth of data which should be of interest to those concerned with the etiology of cancer, carcinogenic agents, industrial and occupational diseases, skin cancer, vital statistics and others. The style of writing is not always easy, but the value of the material far outweighs this defect. This study is an example of a method which might profitably be more widely used to reveal exogenous causes of human cancers.

Renal Hypertension. By Eduardo Braun-Menéndez, Juan Carlos Fasciolo, Luis F. Leloir, Juan M. Muñoz, and Alberto C. Taquini. Translated by Lewis Dexter, M.D. Fabrikoid. Price, $6.75. Pp. 451, with 91 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill. 1946.

The Argentine (1943) edition was reviewed in THE JOURNAL Dec. 2, 1944, page 926. This edition is offered as a summary in English of present day knowledge of renal hypertension. The translator has incorporated material from one hundred and twenty-four papers which appeared during 1944 and 1945. The translation is therefore not line for line, although traces of Iberian sentence structure persist. Most of the minor errors of the former edition have been amended. Format and typography are improvements on the original. The book is recommended as a compendium for investigators whose critical familiarity with the field enables them to form more objective concepts than are presented by the authors. The clinician will find the book useful chiefly as an excellent bibliographic file in renal hypertension.

A Handbook of Radiography. By John A. Ross, M.A., M.R.C.S., L.R.C.P., Radiologist, General Hospital, Warrington, England. Second edition. Cloth. Price, 10s. 6d. Pp. 165, with 92 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W. C. 1, 1946.

This is a rather elementary and brief technical manual on roentgenography suitable for the instruction of x-ray technicians and for guidance for physicians so situated that they must utilize x-rays in diagnostic work without having the benefit of properly trained technical help. The illustrations consist of line drawings.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

DANGER OF DDT IN KITCHENS

To the Editor:—We have been using DDT for spraying the hosiptal's kitchens and dining rooms for the control of flies. The safety of this procedure has been questioned. Is there a possibility of harm to persons eating food prepared in the kitchens and served in the dining room?

B. Earl Clarke, M.D., Providence, R. I.

Answer.—It is not clear what method of spraying has been used by the inquirer. The degree of hazard is influenced to some extent by the method of application. Since DDT has been shown to be capable of producing chronic toxicity in animals when added to their diet even in small amounts, every effort should be made to keep this substance out of human food. It should not be allowed to contaminate food, cooking or eating utensils or table tops. Such contamination can generally be avoided by applying the spray directly to the ceiling and walls.

TREATMENT OF SPLENOMEGALY

To the Editor:—A patient with moderately advanced Banti's disease has a palpable spleen which extends to the umbilicus. The patient has been advised that nothing more can be done. Would epinephrine in oil or splenectomy be of any value at this stage?

W. J. Klinck, M.D., Lennoxville, Quebec.

Answer.—Epinephrine in oil might have a transient effect on the peripheral blood picture, but it would not have value in the treatment of Banti's disease. Most authors feel that splenectomy is beneficial when performed in the early stages of the disease before the liver function is seriously impaired. The mechanical effects of a large tumor are removed and less blood flows through the portal system, thus lessening the chance of bleeding. In many cases, however, the results of splenectomy are unsatisfactory and the course of the disease is unaltered.

THIOURACIL FOR HYPERTHYROIDISM IN PREGNANCY

To the Editor:—Are there any data concerning the use of thiouracil in hyperthyroidism complicating pregnancy? Are blood changes more apt to occur when the patient taking thiouracil is pregnant? Is there any known effect on the unborn infant?

R. K. Finley, M.D., Dayton, Ohio

Answer.—There are not enough data on the use of thiouracil in hyperthyroidism complicating pregnancy to warrant definite conclusions. The data available indicate that hyperthyroidism responds about the same to thiouracil in women who are pregnant as it does in women who are not pregnant. Leukopenia and agranulocytosis are not more common when the drug is given during pregnancy. There are not sufficient data to state whether or not the drug is harmful to the fetus. The evidence available indicates that it is not.

PRIAPISM IN LEUKEMIA

To the Editor:—Please discuss the treatment of priapism complicating chronic myeloid leukemia. Is thrombosis the cause? If so, would the use of Dicumarol (3,3'-methylene-bis-[4-hydroxycoumarin]) be justified in spite of the tendency to hemorrhage?

C. E. McCarthy, M.D., Clinton, Tenn.

Answer.—Priapism, a relatively uncommon symptom of leukemia, has been ascribed to thrombosis, leukocytic stasis or leukemic infiltration in the corpora cavernosa. Radiation treatment of the leukemia often relieves the local symptom. Should there be recurrences of priapism after the leukocyte count is reduced, a trial with Dicumarol is justified. Only in the late stages of chronic myeloid leukemia is there a lowering of the platelets with a tendency to hemorrhage. Dicumarol would be contraindicated in such cases.

COFFEE AND CORONARY DISEASE

To the Editor:—Is there any definite proof that coffee is contraindicated in coronary disease and Buerger's disease?

Axel W. Swenson, M.D., Van Nuys, Calif.

Answer.—No. Nor is there any proof that it is of benefit, although one might suppose that the vasodilatation produced by caffeine might be of slight value.

FALSE POSITIVE SEROLOGIC REACTIONS FOR SYPHILIS AFTER TROPICAL DISEASES

To the Editor:—Several soldiers who had tropical ulcers or jungle rot in the South Pacific have had positive Wassermann tests after their return, varying from 1 plus to 3 plus. Serologic tests were negative before they had the disease, and history of sexual contact or chancre is denied. After repeated tests the Wassermann test gradually becomes negative. Is there any literature or direct information on this subject? It is extremely embarrassing for these men to return to their wives and try to convince them that they have not had any outside family contacts.

M.D., Wisconsin.

Answer.—"Tropical ulcers" so called, or "jungle rot," are not in themselves known to produce positive blood serologic tests for syphilis. They may, of course, be complicated by syphilis. The term "tropical ulcer" as such is used for a specific clinical entity of uncertain and possibly varying etiology (Manual of Tropical Medicine, National Research Council, Philadelphia, W. B. Saunders Company, 1945, p. 475). It is also used in a more general sense to include several tropical diseases which may produce skin ulceration (e. g. leishmaniasis, oriental sore, kala azar or even granuloma inguinale). These are occasionally known to produce biologic false positive reactions for syphilis (Stokes, Beerman and Ingraham: Modern Clinical Syphilology, Philadelphia, W. B. Saunders Company, 1944, p. 87, fig. 33).

The first requisite, of course, when confronted with a patient with a positive blood serologic test is to rule out syphilis. If this cannot be done by the usual procedures, the patient should be treated for this disease.

On the other hand, the fact that the tests reported on the cases cited are only weakly positive and that they revert to negativity in a relatively short time indicates that they are probably nonspecific positives unrelated to syphilis. (For complete recent review of this subject see Herman Beerman: Biologic False Positive Reactions to Tests for Syphilis, *Am. J. M. Sc.* **209**:525 [April], 524 [Oct.] 1945.) Such cases in the absence of other evidence of syphilis should be observed over periods of as much as four to six months at two to four week intervals. The blood should preferably be studied by quantitative procedures in order to determine the exact amount in units of reagin present in order to detect significant trends. Treatment for syphilis should not be given on the basis of weakly positive serologic tests alone, in the absence of other evidence of the disease or a definite history of infection.

A number of causes other than syphilis for positive blood serologic tests among veterans recently returned from the South Pacific are known, among the most common being:

1. Inoculation to produce immunity against various infectious diseases. Soldiers who are working in the South Pacific area receive inoculations on an average of once every six months and at times, when exposed to epidemic conditions, more frequently. It is common practice also to have the medical records reviewed at the time of discharge and for the soldiers to be given a series of inoculations against infectious diseases at that time. The nonspecific positive reactions for syphilis when they occur in these circumstances are transitory, appearing within two weeks of the date of vaccination or inoculation and disappearing in most instances within two months or persisting occasionally as long as four months. The effects of these inoculations could accordingly be carried into the first few months of civilian life. Considerable interest in recent years has centered about nonspecific positive reactions for syphilis from immunization. Some of the more important references on this subject being:

USE OF METREURYNTER

To the Editor:—A primapara aged 28 was seen because of uterine bleeding. She gave a history of menorrhagia for a few weeks on and off and of previous operative intervention by a physician, the nature of which was unknown. Following this procedure there was intermittent uterine bleeding for a few weeks and progressive weakness. Vaginal examination under aseptic precautions revealed an enlarged and soft uterus, no palpable mass inside the uterus or elsewhere, and an open cervix with oozing of blood. The patient complained of tenderness over both lower quadrants and over the abdomen. A vaginal pack was inserted, and she was advised to stay in bed. On the next day, when the pack was removed, there was very little blood. Ergonovine was given, one tablet three times daily for two days. The patient did not return for seventeen days but stated that the bleeding continued during this period and that she did not stay in bed. Reexamination again showed an open cervix with bleeding. A vaginal pack was inserted daily for the next three days and ergonovine was repeated, one tablet every four hours. The patient refused to stay in bed, and the bleeding persisted. Because of the persistent bleeding a 1 inch Voorhees bag was inserted on the fourth day with an attached weight. In twenty-four hours the Voorhees bag came out with a few clots. Fifteen minutes later a mass the size of a small grapefruit was passed, along with what appeared to be membrane from the placenta. Following this the bleeding stopped. An Aschheim-Zondek test was not done in this case because of the uterine bleeding. Was an Aschheim-Zondek test necessary in this case? Is an Aschheim-Zondek test misleading at times, since other conditions besides pregnancy can give a positive test? Can the results of the Ascheim-Zondek test be misleading as a result of the way some patients collect their urine? Is there any reason why a metreurynter should not have been used in such a case of uterine bleeding with a history of previous surgical intervention of unknown type?

M.D., Connecticut.

Answer.—If the patient was only two or three months pregnant the simplest way of emptying the uterus probably would have been dilation of the cervix and curettement of the uterus, provided the cervix was soft. If the cervix was firm, either a small metreurynter such as was used or a cervical gauze pack would be proper therapy because both of these foreign bodies cause softening and dilatation of the cervix and subsequent expulsion of the products of conception. In this case it would have been advisable to perform a curettage after the spontaneous expulsion of the masses to make certain that no placental or membranous tissue remained in the uterus.

A positive Aschheim-Zondek test nearly always indicates a living conceptus, especially a living fetus. However, even in the presence of a dead baby the Aschheim-Zondek test may be positive if the placenta has living chorionic ectoderm. On the other hand, in early pregnancies there may be a negative biologic test in the presence of a living embryo. Occasionally, but not often, a positive Aschheim-Zondek test is obtained in the absence of a pregnancy.

Nearly all textbooks of obstetrics contain descriptions of the use of metreurynters aided by illustrations. Two of the best are De Lee and Greenhill's Principles and Practice of Obstetrics (ed. 8, Philadelphia, W. B. Saunders Company) and Stander's Textbook of Obstetrics (New York, D. Appleton-Century Company).

TREATMENT OF GIARDIA LAMBLIA INFECTION

To the Editor:—A girl aged 3 years developed diarrhea in August 1945. Examination of the stools revealed Giardia, mucous threads and blood. Bowel movements occur two to three times a day but the diarrhea becomes worse if a proper diet is not followed. There has not been fever or pain. The patient does all right under medication with bowel antiseptics. What is the latest treatment of flagellate dysentery (giardiasis)?

M.D., Missouri.

Answer.—The most effective treatment for Giardia lamblia infection thus far reported is the use of quinacrine hydrochloride (atabrine dihydrochloride). Therapy for an adult consists in the oral administration of one tablet, 0.1 Gm. (1½ grains), of quinacrine three times daily for five days. The dosage for a 3 year old child should be reduced accordingly. No untoward reactions to the drug have been observed, although the number of stools may be increased during the first several days of medication. The infection usually is controlled rapidly and Giardia may disappear from the stools after only one or two days of therapy. A second course of quinacrine may be necessary after an interval of seven to ten days. Less frequently Giardia lamblia infection may persist after several courses of therapy with quinacrine.

Giardia lamblia organisms are not known to invade tissue. They do not produce bloody stools, although diarrhea is not an uncommon symptom. In the present case, therefore, it seems highly improbable that they are responsible for the bloody stools.

RECURRENT DISLOCATION OF THE MANDIBLE

To the Editor:—A patient has had thirty or forty dislocations of the mandible in the past year and a half following a difficult tooth extraction. The dentist had to force the mouth open vigorously. The jaw went out of place and apparently the capsule was so stretched that the dislocation has been recurring. Recently general anesthesia has been necessary for reduction because of severe pain. Has the method of injecting a sclerosing solution into the capsular ligaments to produce contraction been successful? What type of solution has been most successful and what is the technic?

A. A. Skemp, M.D., La Crosse, Wis.

Answer.—In recurrent dislocation (or subluxation) of the mandible, simple treatment should be instituted early. After the second dislocation of the mandible interdental wiring (or elastics), a chin strap or other device to limit the opening of the mouth should be applied for several months. If this procedure proves to be inadequate, as it frequently does, the temporomandibular joint should be injected with a sclerosing solution. The results have been encouraging. The technic briefly is as follows: With the mouth open, a 1½ inch long 26 gage needle, on a 1 cc. tuberculin syringe is inserted into the temporomandibular joint posterior to the head of the condyle in a slightly upward and inward direction until contact is made with the mesial wall of the glenoid fossa. The penetration of the needle will be 2 to 3 cm. The needle is withdrawn about 0.5 cm., and 0.25 to 0.5 cc. of a 5 per cent aqueous solution of sodium psylliate mixed with an equal portion of 2 per cent procaine hydrochloride is injected. Sometimes several injections about ten days apart are necessary. The following references discuss the injection and surgical treatment of this disorder:

ROENTGEN THERAPY OF RHEUMATOID SPONDYLITIS

To the Editor:—Recently I have been informed that there has been success in the high voltage x-ray irradiation of the Pierre Marie Strümpell type of arthritis. How much benefit is derived from treatment of this kind?

M.D., Quebec.

Answer.—Roentgen therapy has been employed in the treatment of different forms of rheumatic disease; the best results have been observed in cases of rheumatoid arthritis of the spine (Marie-Strümpell spondylitis). The technic usually employed is conventional high voltage x-ray therapy with factors 140 to 200 kilovolts, 50 cm. skin-target distance and 0.5 mm. copper and 1 mm. aluminum skin filters, and treatment is given to as many ports as needed to include the spine and paraspinous tissue involved in the disease, approximately 150 roentgens administered to each port on alternate days until 450 roentgens have been delivered to each port. It is best to treat only two or three ports on the same day. It is often necessary to repeat such treatment two or three times at intervals of four to six weeks. Scott has reported excellent results from the use of low voltage, wide field "superficial" roentgen therapy for this disease. Caution must be exercised in irradiating over the pelvis in young women in order that damage to the gonads may not occur.

The mechanism by which benefit is derived from roentgen therapy in this disease has not been explained, but several investigators have reported good results and most physicians who have properly employed it believe x-ray therapy superior to other measures to relieve the pain and muscle spasm of rheumatoid spondylitis. To determine whether the course of the disease is favorably altered, more prolonged observation of treated patients will be required. Best results are obtained in the earlier stages of the disease; x-ray therapy is of little value in the later stages when pain and muscle spasm are of minor importance, when the facets are ankylosed and the spinous ligament calcified.

Roentgen therapy is not complete treatment for rhizomelic spondylitis. Other valuable measures of treatment are required for best results.

Smith, Boland and Hench recently reported good results from roentgen therapy for rheumatoid spondylitis observed in a rigidly controlled study of different forms of treatment of early cases among military personnel. A discussion of the value and limitations of this form of therapy is contained in a recent report by Freyberg.

THE VAGINAL SMEAR

Practical Applications in the Diagnosis of Cancer of the Uterus

JOE V. MEIGS, M.D.
Boston

In 1928 Papanicolaou[1] demonstrated his ability to make a diagnosis of cancer of the uterus by the observation of single malignant cells cast off from the tumor into the vaginal secretion. This was a cytologic diagnosis rather than a diagnosis made by a study of the architecture of the tissue, such as is done by pathologists. Subsequently, in 1941 and 1943, Papanicolaou and Traut[2] published articles and a monograph describing their experiences. The monograph, illustrated by many plates of benign and malignant cells, suggested to the medical profession that their method was a success and should be used. In 1943 Meigs and others,[3] confirming the work of Papanicolaou, reported a series of cases studied at the Massachusetts General Hospital and in 1945, in a second article,[4] gave convincing evidence of the value of the method. At present 2,749 cases with an error of only 3.2 per cent have been studied.

It is obvious to those who are interested in uterine cancer that this method is of extreme value in enabling the physician, if not to make a definite diagnosis, at least to screen satisfactorily women who come for routine examination. A positive smear indicates that careful further studies both by smear and by biopsy are indicated. A negative smear indicates that at the time it was taken cancer cells were not found on the slide. If the patient's symptoms or the appearance of the cervix is suggestive, more smears must be taken because there is convincing evidence that in certain instances shedding of the cells does not occur. Six and one-tenth per cent of 339 cancers did not show malignant cells. The positive smear is an indication that further investigation must be carried out until proof of cancer is found. Without other corroborative evidence I have rarely allowed a positive vaginal smear to be the sole reason for radical surgery The smear diagnosis is important and its value has been definitely settled, but how far one is to go in the treatment of patients with a positive smear and a negative biopsy has not yet been decided.

It has been suggested that smears be taken directly from the cervix and by use of a cannula from the endocervix and endometrial cavity. This is a splendid idea and without question it is of greater value in some instances than the vaginal smear, but this method loses the importance of the simplicity of the vaginal smear technic. The real value of the vaginal smear is the ease with which it can be made by general practitioners in their offices. Those who can easily carry out the more complicated method, should do it in addition to making the vaginal smear. The vaginal secretion, although it is more dilute than that removed directly from either the cervix or the endometrial cavity, gives one a greater chance to find cast-off cancer cells because all cells, not merely the cells aspirated from a small area of cervix and endometrium are shed into the vaginal secretion. There is no objection to cervical or endometrial smears, but on the whole for the purposes here mentioned greater concentration on the vaginal smear method will produce better results. The vaginal smear is taken by means of a small glass tube and a rubber bulb. The tube is placed in the vagina with the bulb compressed, the bulb is then released and the vaginal secretion removed by suction. The secretion is then blown on a glass slide, spread out with the tip of the glass tube to make a good film and then placed immediately in a solution of one part ether and one part 95 per cent alcohol. Smears may remain in the fixation two to three weeks without showing any signs of deterioration. It is important that the slide be placed in the fluid immediately after the secretion has been placed on the slide so that the maximum benefit of fixation may be secured. This is a simple method, and if it is complicated by the necessity of the use of speculums and cannulas it will defeat its own purpose, which is simplicity and accuracy.

In this paper it is not necessary to give the directions for staining methods or the method of diagnosis of individual cells. This has been included in numerous articles and in Papanicolaou and Traut's monograph, which can be easily obtained. However, there are a few characteristics of the cells which are extremely important. The nucleus of the cell is the main diagnostic criterion. The cancer cell has a large abnormal nucleus, and in groups a variation in size and shape is obvious. The large nuclei of cells from cervical cancer are radically different from those of the normal cells of the cervical epithelium. It is important to note the paucity of cytoplasm compared to the amount seen in the normal cell. In the cancer cell the large nucleus takes up most of the cytoplasmic space and the ratio of nucleus to cytoplasm is different from that in the normal cell In cancer of the endometrium the same criteria

---

secretion. The result of a vaginal smear was reported as doubtful. The bleeding and discharge persisted under treatment. However, two subsequent vaginal smears were positive. A dilation and curettage were performed and showed adenocarcinoma of the endometrium.

These 2 cases of uterine cancer, 1 cervical and 1 endometrial, emphasize the importance of the vaginal smear in the detection of early cancer. Neither of the cases was suggestive enough clinically to warrant biopsy, and both would have been missed except for the routine vaginal smear.

There is a special group of cases in which the vaginal smear method is of real practical value. These are cases of carcinoma treated in the past by radiation, in which the patients are watched routinely in the tumor clinic for possible recurrence of their disease. The importance of the vaginal smear method in this instance is illustrated by the 2 following case reports.

N. O., a woman aged 51, was given routine roentgen ray and radium therapy for an epidermoid carcinoma of the cervix, grade 2, stage 2, in 1941. On routine follow-up in the tumor clinic she had repeatedly positive smears over a period of six months in 1944. During this time she had no symptoms and was considered negative on clinical examination. One biopsy during this interval was reported as revealing "chronic inflammation." Six months after the first positive vaginal smear, tissue obtained from the vaginal vault with great difficulty, under anesthesia, showed epidermoid carcinoma of the cervix.

M. M., a woman aged 77, was given routine roentgen ray and radium therapy in 1944 for an epidermoid carcinoma of the cervix, grade 3, stage 3. On routine follow-up in the tumor clinic she had repeatedly positive smears over a period of eleven months. Evidence of disease could not be seen clinically and a suggestive area could not be detected for biopsy. The patient was asymptomatic. Eleven months after the first positive vaginal smear, a specimen for biopsy secured from the apex of the vagina showed epidermoid carcinoma of the cervix.

This type of case points out the importance of the vaginal smear in the routine examination of the Gynecological Tumor Clinic. In both these cases it was impossible to tell clinically whether disease was present. It is difficult to obtain specimens for biopsy from irradiated patients, and some screening method by which certain cases can be chosen for further study is of great value. It should be pointed out that the diagnosis by vaginal smear in this group of irradiated patients is more difficult than that of untreated patients. However, with careful study few false positive or negative smears will be reported in this group.

The next 2 cases are representative of a real problem. These are 2 patients who had clinically suspicious cervices and vaginal smears positive for cancer cells but in whom biopsies were negative. The question of whether radical surgical intervention should be performed in such instances is still unanswered.

M. S., a 35 year old woman who had four children, came to a private physician's office with the chief complaint of intermenstrual spotting of five to six weeks' duration. Pelvic examination revealed a lacerated cervix. Three vaginal smears were reported positive. Two specimens for biopsies taken at the same time as vaginal smears were made were reported as indicative of acute and chronic endocervicitis. A radical hysterectomy was performed. The final pathologic diagnosis was carcinoma in situ of the cervix.

L. S., a 45 year old woman who had two children, came to a private physician's office for routine physical examination. At pelvic examination, the cervix presented a normal appearance. The patient had had a supravaginal hysterectomy some years previously. A routine vaginal smear was positive for cancer cells. Biopsy showed only chronic cervicitis. A cervicectomy was performed. The final pathologic diagnosis was carcinoma in situ.

It is important to note that there is a certain group of early cases in which the diagnosis by vaginal smear is more accurate than that by biopsy. If the cervix presents a generally suspicious appearance it is difficult to know what portion to use for biopsy. For this reason even repeated biopsies may not disclose abnormalities. The problem of treatment in this type of case is especially important; if cancer is present, it is in an early stage and is curable.

The last report is that of an unusual case in which the vaginal smear was the only method of making a diagnosis.

R. W., a woman aged 80 who had had nine children, came to a private physician because of symptoms referrable to a leukoplakia of the mouth. She was given estrogen therapy, and three days later vaginal bleeding developed. A routine vaginal smear was positive. Since a Le Fort operation for prolapse had been performed fourteen years previously, she could not be properly examined pelvically. At operation the Le Fort colpoplasty was taken down, the cervix was visualized and a specimen for biopsy was taken. The biopsy was reported as epidermoid carcinoma, grade 4.,

This case has been presented merely as an example of the aid which the vaginal smear may render in diagnosis when pelvic examination is impossible.

CONCLUSIONS

1. The diagnosis of cancer of the cervix and of cancer of the endometrium can be made with a high percentage of accuracy by the vaginal smear method, as first suggested by Papanicolaou.
2. The diagnosis in patients with cancer of the uterus can be missed by this method if the tumor does not shed tumor cells.
3. The method should be of tremendous value in the routine screening of patients either in the clinic or in the hospital.
4. Early cases of cancer, i. e. "cancer in situ," can be diagnosed by this method.
5. A positive vaginal smear should not be regarded as an indication for hysterectomy. It should indicate that specimens for biopsy should be taken so that the pathologist may confirm the observations disclosed by the vaginal smear.
6. This method is not an office procedure; it should be interpreted by those trained in cytology and in the smear method of making a diagnosis.

ABSTRACT OF DISCUSSION

DR. WARREN C. HUNTER, Portland, Ore.: The author mentioned the reluctance of pathologists to examine material other than in form for biopsy, stating that they have been trained to depend on pattern in evaluating the malignant state of tissue. Naturally, one does prefer continuity and pattern, but there is no reason for a refusal to try other methods of diagnosis merely because of preference. For a long time, pathologists have been asked to look for cancer cells in transudates and have found them on occasion. Actually, there is nothing mysterious about the cytologic method. Any cell reaching the surface, whether normal or abnormal, is cast off and may retain its form long enough to be stained and identified. Even in tissue sections one pays attention to individual cell structure in addition to tissue pattern, degree of differentiation, polarity of cells and heterotopia as evidences of neoplasia. The cytologic features of tissue sections are equally applicable to single cancer cells and to groups of such cells. My experience with the method began about eighteen months ago. One soon becomes able to spot cancer cells in surveying smears under low power magnification by such important features as nuclear hyperchromatism and reduced nuclear cytoplasmic ratio, just as easily as one makes are true but there is less variation in the size and shape of the nucleus and less evidence of a differing in size from the normal nucleus. Yet the difference is real and can be observed. The presence of histiocytes and many leukocytes is a suspicious observation but is not diagnostic. The presence of blood is important, but its absence does not indicate a negative diagnosis. The most important observation is the abnormal nucleus *and its size in relation* to that of the rest of the cell. Diagnosis by means of the vaginal smear is a cytologic one, and any one with a good background in histology and cytology can be trained to be a satisfactory technician. It is difficult for the pathologist to be interested in this method, for he is trained to observe the relation of cells to architecture and the importance of invasion. Diagnosis by vaginal smear is painstaking and slow, and twenty minutes is not too long for the examination of a slide. Cases have been missed in the laboratory; yet after a review of the slide one or two cells were found that had been missed because the cytologist had not covered the entire slide the first time. Well trained technicians should be used to screen out negative slides, but in the process of screening suspicious cells should be noted, marked and presented to the expert for final decisions.

Cancer of the Cervix.—It is easier to diagnose cancer of the cervix than cancer of the endometrium. It is obvious that the individual cancer cells are cancer cells, and even though the tumor cannot be found at biopsy, nevertheless it must be there. There is such a definiteness about a positive cervical cancer cell that even if tumor is not found on multiple sections it would take complete serial sections to prove it was not present. It is quite possible, for it is known that one can make the diagnosis of "cancer in situ," that there is a time when the cancer is not over a few cells in size and it would be impossible for the pathologist to find it unless all the endocervix and squamous portion were observed under the microscope. This is as a rule impossible because of inability to spend the time and the money for serial sections. It is sad to think that it cannot be proved that positive cells mean cancer. If one could prove that a positive cell seen in a vaginal smear means cancer, even though infinitesimal, what a great advance would have been made! Nineteen slides have been called positive, but the pathologist has not been able to find the cancer. The cells were definite; yet they had to be called mistakes because the department of pathology has been unable to find the tumor. This is not the fault of the pathologist, for they have been extremely cooperative and have cut hundreds of sections, some of them serially; nevertheless it is essential in such a case that every single bit of cervical epithelium be viewed because it is felt that the cancer must be there. The number of errors for false positive smears is now at 2.0 per cent. That this is not a true picture is a definite fact in the opinion of those in the laboratory, but there is little one can do about it at this time. In the future it will be necessary to be much more exhaustive in the histologic study of the cervical epithelium.

In a certain group of patients a slide has been called negative when there was tumor in the cervix. This is explained by the fact that the tumor presumably did not shed cells. Perhaps the patient had just had a douche. It is impossible to make a diagnosis if the cells are not present, just as it is impossible for the pathologist to find tumor in a piece of tissue that has been removed from a noncancerous area. The pathologist does not call it a mistake when he says "no tumor present," even when it is obvious clinically that a tumor exists, for when he does the biopsy or cuts the block of tissue cancerous material may not be on his slide. Thus it is possible for the cytologist to miss cancer when it is present in the patient. In 3.5 per cent of the cases of cervical cancer in which the slides were called negative, re-observation still did not show signs of tumor cells on the slides. The diagnosis cannot be made if there is no shedding of cells, if there are no cells on the slides or if not even a small number of cells are seen in the study of the slide. This is a definite hazard of the smear method, but histologic examination of tissue presents the same problem.

Cancer of the Endometrium.—In the diagnosis of cancer of the endometrium the same problems are encountered, but there is an occasional confusion in calling cells malignant that are definitely not cancerous, and vice versa. It is because there is not a great deal of difference between normal and malignant endometrial cells. The diagnosis of endometrial cancer calls for more expert observation than does that of cancer of the cervix. It can be made and the figures are improving but the problem is difficult. The error of false negative observations in endometrial cancer is 20 per cent. Of 80 cases of proved endometrial cancer, 16 negative smears were reported and 12 of these did not show malignant cells on reexamination. These mistakes are subject to the same criticism as are the false negative group in cancer of the cervix, though the percentage is much higher. This may be explained partially by degeneration of the malignant cells from endometrial cancers before they are shed in the vaginal secretion. The more familiar the cytologist becomes with the diagnostic criteria the more accurate he becomes in his diagnostic acumen.

There can be no doubt of the value of the vaginal smear in the diagnosis of cancer of the cervix and of the endometrium. It should be an accepted fact everywhere that the diagnosis can be made this way. There are many advances to be made by this method of cancer research, the most important of which is its aid in making an early diagnosis and thereby permitting earlier and more satisfactory methods of treatment. The practical aspects of the problem will be presented in a few case reports demonstrating the value of the vaginal smear in the diagnosis of cancer in the early stages and in others when the diagnosis was made by smear in totally unsuspected cases.

In the series of 2,749 cases are included 339 cases of cancer. In 25 of these cases either carcinoma was unsuspected before a vaginal smear was taken or the vaginal smear was of great aid in the primary diagnosis.

REPORT OF CASES

Reports of 2 totally unsuspected cases of cancer follow:

E. W., a 30 year old woman who had two children, came to the outpatient department with the chief complaint of pain in the right lower quadrant of the abdomen. A pelvic examination was entirely negative. A routine vaginal smear was reported as positive. A biopsy was made two weeks later and was reported indicative of chronic cervicitis. A subsequent biopsy four days later showed epidermoid carcinoma of the cervix, grade 2. A radical hysterectomy was performed.

C. H., a woman aged 68, came to a private physician's office with the chief complaint of slight vaginal bleeding and discharge. Clinically nothing abnormal was seen except senile vaginitis, and many Trichomonas vaginalis were found in the vaginal secretion. The result of a vaginal smear was reported as doubtful. The bleeding and discharge persisted under treatment. However, two subsequent vaginal smears were positive. A dilation and curettage were performed and showed adenocarcinoma of the endometrium.

These 2 cases of uterine cancer, 1 cervical and 1 endometrial, emphasize the importance of the vaginal smear in the detection of early cancer. Neither of the cases was suggestive enough clinically to warrant biopsy, and both would have been missed except for the routine vaginal smear.

There is a special group of cases in which the vaginal smear method is of real practical value. These are cases of carcinoma treated in the past by radiation, in which the patients are watched routinely in the tumor clinic for possible recurrence of their disease. The importance of the vaginal smear method in this instance is illustrated by the 2 following case reports.

N. O., a woman aged 51, was given routine roentgen ray and radium therapy for an epidermoid carcinoma of the cervix, grade 2, stage 2, in 1941. On routine follow-up in the tumor clinic she had repeatedly positive smears over a period of six months in 1944. During this time she had no symptoms and was considered negative on clinical examination. One biopsy during this interval was reported as revealing "chronic inflammation." Six months after the first positive vaginal smear, tissue obtained from the vaginal vault with great difficulty, under anesthesia, showed epidermoid carcinoma of the cervix.

M. M., a woman aged 77, was given routine roentgen ray and radium therapy in 1944 for an epidermoid carcinoma of the cervix, grade 3, stage 3. On routine follow-up in the tumor clinic she had repeatedly positive smears over a period of eleven months. Evidence of disease could not be seen clinically and a suggestive area could not be detected for biopsy. The patient was asymptomatic. Eleven months after the first positive vaginal smear, a specimen for biopsy secured from the apex of the vagina showed epidermoid carcinoma of the cervix.

This type of case points out the importance of the vaginal smear in the routine examination of the Gynecological Tumor Clinic. In both these cases it was impossible to tell clinically whether disease was present. It is difficult to obtain specimens for biopsy from irradiated patients, and some screening method by which certain cases can be chosen for further study is of great value. It should be pointed out that the diagnosis by vaginal smear in this group of irradiated patients is more difficult than that of untreated patients. However, with careful study few false positive or negative smears will be reported in this group.

The next 2 cases are representative of a real problem. These are 2 patients who had clinically suspicious cervices and vaginal smears positive for cancer cells but in whom biopsies were negative. The question of whether radical surgical intervention should be performed in such instances is still unanswered.

M. S., a 35 year old woman who had four children, came to a private physician's office with the chief complaint of intermenstrual spotting of five to six weeks' duration. Pelvic examination revealed a lacerated cervix. Three vaginal smears were reported positive. Two specimens for biopsies taken at the same time as vaginal smears were made were reported as indicative of acute and chronic endocervicitis. A radical hysterectomy was performed. The final pathologic diagnosis was carcinoma in situ of the cervix.

L. S., a 45 year old woman who had two children, came to a private physician's office for routine physical examination. At pelvic examination, the cervix presented a normal appearance. The patient had had a supravaginal hysterectomy some years previously. A routine vaginal smear was positive for cancer cells. Biopsy showed only chronic cervicitis. A cervicectomy was performed. The final pathologic diagnosis was carcinoma in situ.

It is important to note that there is a certain group of early cases in which the diagnosis by vaginal smear is more accurate than that by biopsy. If the cervix presents a generally suspicious appearance it is difficult to know what portion to use for biopsy. For this reason even repeated biopsies may not disclose abnormalities. The problem of treatment in this type of case is especially important; if cancer is present, it is in an early stage and is curable.

The last report is that of an unusual case in which the vaginal smear was the only method of making a diagnosis.

R. W., a woman aged 80 who had had nine children, came to a private physician because of symptoms referrable to a leukoplakia of the mouth. She was given estrogen therapy, and three days later vaginal bleeding developed. A routine vaginal smear was positive. Since a Le Fort operation for prolapse had been performed fourteen years previously, she could not be properly examined pelvically. At operation the Le Fort colpoplasty was taken down, the cervix was visualized and a specimen for biopsy was taken. The biopsy was reported as epidermoid carcinoma, grade 4.,

This case has been presented merely as an example of the aid which the vaginal smear may render in diagnosis when pelvic examination is impossible.

CONCLUSIONS

1. The diagnosis of cancer of the cervix and of cancer of the endometrium can be made with a high percentage of accuracy by the vaginal smear method, as first suggested by Papanicolaou.
2. The diagnosis in patients with cancer of the uterus can be missed by this method if the tumor does not shed tumor cells.
3. The method should be of tremendous value in the routine screening of patients either in the clinic or in the hospital.
4. Early cases of cancer, i. e. "cancer in situ," can be diagnosed by this method.
5. A positive vaginal smear should not be regarded as an indication for hysterectomy. It should indicate that specimens for biopsy should be taken so that the pathologist may confirm the observations disclosed by the vaginal smear.
6. This method is not an office procedure; it should be interpreted by those trained in cytology and in the smear method of making a diagnosis.

ABSTRACT OF DISCUSSION

DR. WARREN C. HUNTER, Portland, Ore.: The author mentioned the reluctance of pathologists to examine material other than in form for biopsy, stating that they have been trained to depend on pattern in evaluating the malignant state of tissue. Naturally, one does prefer continuity and pattern, but there is no reason for a refusal to try other methods of diagnosis merely because of preference. For a long time, pathologists have been asked to look for cancer cells in transudates and have found them on occasion. Actually, there is nothing mysterious about the cytologic method. Any cell reaching the surface, whether normal or abnormal, is cast off and may retain its form long enough to be stained and identified. Even in tissue sections one pays attention to individual cell structure in addition to tissue pattern, degree of differentiation, polarity of cells and heterotopia as evidences of neoplasia. The cytologic features of tissue sections are equally applicable to single cancer cells and to groups of such cells. My experience with the method began about eighteen months ago. One soon becomes able to spot cancer cells in surveying smears under low power magnification by such important features as nuclear hyperchromatism and reduced nuclear cytoplasmic ratio, just as easily as one makes out immature blood cells in a blood film. Other important features, such as the lack of individual cell boundaries, are likewise readily appreciated under low power magnification. Familiarity with individual cancer cells opens a new vista of cellular pathology in tissue sections, in that one sees finer details than one ever thought existed when studying cells en masse. As the author brought out, there are drawbacks to the method. At present there are too few physicians and too few technicians to carry the load. Some smears can be examined in a few minutes. The questionable ones may take thirty or even forty-five minutes. Then, too, postradiation changes are on occasion rather troublesome. I have not yet tried the modification of Ayre, mentioned by Dr. Traut. The original method has been modified somewhat in that a tube is not used but the material is taken on the speculum and then the smears are made, the remainder being placed in alcohol-ether, embedded in paraffin, sectioned and stained by the Papanicolaou method so that both smears and sections are available.

Dr. Joe Vincent Meigs, Boston: I enjoyed Dr. Rubin's paper. He has done something that is of extreme value. I cannot but believe, as I see patients in my office and know that some of them have menstruated from the age of 14 until they are 24 or 26 before they tried to have children, that to add contraception to that insult to nature is wrong. I think that lack of child bearing accounts for a number of cases of endometriosis. The comparison of private patients who have their first babies at the age of 26 or 27 and the patients seen in charity wards who have their babies when they are 18 and 19 is very striking. A great deal of attention should be paid to what Dr. Rubin says. Physicians ought to advise girls who are just married to have children and not try to teach them how not to.

MEASURES FOR THE PROTECTION OF NEWBORN INFANTS

I. Description of Measures Instituted in May 1937 at Long Island College Hospital

CHARLES A. WEYMULLER, M.D.
ALFRED C. BECK, M.D.
and
ELIZABETH J. ITTNER, M.D.
Brooklyn

Because the newborn infant is particularly susceptible to certain types of infection, special precautions must be taken for his protection as well as for that of his companions in the nursery. All have become familiar with the fact that epidemics can and do occur in nurseries for newborn infants, even in elaborately equipped hospitals of the highest professional standing. Most publicized among the conditions that cause such epidemics is the dreaded diarrhea of the newborn. This disease sometimes carries a mortality rate as high as 80 per cent and taxes to the utmost the resources of the most expert pediatricians. Because exhaustive researches have not disclosed its cause or the means of its transmission, its control is exceedingly difficult even under ideal conditions. The only effective weapon in combating this scourge of modern nurseries is a meticulous technic of isolation rigidly applied to infants who have been afflicted with the disease or who have been exposed to it.

Far more important, though usually less dramatic, are infections of the skin, of the respiratory tract, of the eyelids and even of the eyes. Because of the prophylaxis, only 1 case of gonorrheal ophthalmia has occurred among the newborn infants of the Long Island College Hospital during the past twenty years, although many of their mothers had gonorrhea. On the contrary, cutaneous and respiratory infections have not been rare; they tend to spread rapidly from patient to patient and may become generalized and result in general sepsis. Although chemotherapy and antibiotic and serum therapy have revolutionized the control of certain varieties of generalized infections, certain other types resist all forms of treatment and end fatally. As a consequence, there is a wholesome horror of these conditions.

As to respiratory infections, no specific prophylactic measures have been adopted, pending the results of studies in progress elsewhere on the use of aerosols and ultraviolet radiation.

However, our routine for the prevention of infection of the skin has been most effective, and will be discussed later in this paper.

This paper, then, will first discuss the factors in spreading infection, and will follow with the corrective measures suggested.

FACTORS IN SPREADING INFECTION

The circumstances that favor the development of the common types of nursery infections are:

1. Unnecessary contact with visitors, nurses and physicians
2. Inadequate isolation of the infants from one another in the nursery
3. Faulty technic for preventing the spread of contamination through (*a*) unsatisfactory nursing assignments, (*b*) common bathing and common weighing facilities, (*c*) inadequate facilities for sterilization of bottles, milk mixtures and other materials used in the care of infants, (*d*) the common utility room and (*e*) the proximity of uncontaminated units to isolation units.

1. Unnecessary contacts, especally with visitors, are an important source of infection. In practically every community in this country the causative agents of the diseases may be introduced into the maternity and nursery units by the mother or her visitors at almost any time. Unfortunately, visitors are a menace of the first magnitude from the point of view of persons attempting to control infection. Yet in some hospitals no restriction is placed on the number of visiting hours or on the number of visitors. It is not unusual for visitors to come to the mother's bedside in uncovered street clothes, and sometimes visitors with severe colds or visible cutaneous lesions are admitted. Frequently there is no age limitation for visitors to the mother, and the children, who are the most frequent hosts and carriers of infection, are permitted to have contacts with the mother. If visitors could be adequately restricted, the desirable goal of close relationship between mother and infant might sooner be realized without the present appalling risks.

To examine nurses carefully and exclude from the nursery any who are found to harbor infection is an elementary precaution that is not universally observed. In many institutions nurses do not wear masks and gowns while caring for infants. Requirements for physicians are subject to precisely the same criticism.

2. Inadequate isolation of the infants from one another is also a possible means of spreading infection. It is common practice to have large nurseries in which in certain instances more than 30 infants are

---

Read before the Section on Pediatrics at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

quartered in a single room. They may be but a few inches apart, and even if they are farther apart their presence in a single large room gives maximum opportunity for the spread of all types of infection to this large group.

3. A third means of spreading infection is its transmission through some intermediary.

a. The primary factor in this spread is the time-honored practice of the blanket assignment of nurses who are on duty in nurseries. That is, a nurse is assigned to certain general tasks, such as the bathing or feeding of a large group of infants or the administration of medication to the entire group. The clearly desirable alternative is the assignment of the entire care of a small group of infants to an individual nurse. It is obvious that each nurse who has a general assignment will have contact with all the babies in a unit, whether the unit is large or small, and that if infection is present she might carry it to all the infants with whom she has contact.

b. Another important item is the common bathing and weighing room. Usually there is but one room for this service in each nursery, and if two nurseries adjoin each other such a room may be used for both nurseries. In any case, every baby in either one or two large units is taken to a central place, which becomes contaminated if and when infection attacks any infant or infants in the group. With such a setup it is inevitable that there should be widespread transmission of infection when it occurs.

c. Similarly, infections spread because of inadequate facilities for sterilization. The usual practice has been to locate the formula room for the preparation of fluids, milk mixtures and materials of all sorts for infants on the same floor as the nurseries or, worse still, adjacent to the children's medical wards. The average formula room is a single room to which utensils are usually returned without sterilization after their use by patients. Naturally, the entire formula room may be contaminated if any infant in any nursery or other unit served by it has become infected. The precautions which heretofore have been relied on as effective are these: Bottles, nipples and utensils are washed and sterilized in the formula room. Once the sterilization has been completed, the room is usually washed with soap and water and the persons who are to prepare the mixtures thereupon follow a technic which is surgically correct in preparation of the milk mixtures and materials. These precautions are worthless, however, for any contamination which has been introduced at any time is still present and contaminates the mixtures under preparation, and eventually the infants to whom they are given. Furthermore, milk and other foodstuffs are taken into the formula room without special handling designed to avoid the introduction of contamination from outside. Of course, pasteurization or autoclaving could obviate such error and is to be recommended.

d. Of particular interest is the common utility room: This ancient institution is even more dangerous as a means of spreading infection than the common bathing and weighing room. Such a room is usually located on the same floor as the nurseries and is used as a storage room for milk mixtures and other materials needed in the nurseries. Before the feedings are given to the infants, the bottles are warmed and the nipples are adjusted in this room. Nurses who use the facilities of the utility room may come from any unit on the floor, perhaps even from the units for the isolation of infected infants and those in the suspect nursery. It is obvious that any contamination which is brought to the utility room from any source must inevitably be widely distributed by all who use that room.

e. Another menace is the proximity of isolation units to uncontaminated units: It is common practice to locate isolation nurseries on the same floor as the uncontaminated nurseries or even to make these isolation facilities an integral part of the uncontaminated nursery setup. Only the perfect isolation technic such as is used in the best managed hospitals for infectious disease can possibly afford protection when such a setup obtains. This perfect technic is rarely employed in maternity hospitals, but certainly could be introduced to general advantage.

CORRECTIVE MEASURES SUGGESTED

In the hope and expectation that we could correct many of the defects noted, we have made extensive changes in the nurseries at the Long Island College Hospital in Brooklyn, which were completed except for one step by May 1937.[1] The service in which these changes have taken place is located in a general hospital in Brooklyn, which cares for about 1,500 infants annually. Before these alterations were made, the routine was similar to that used in first class teaching hospitals. While our results have compared favorably with the best so obtained, they were not satisfactory in our opinion. When infection occurred, its spread could not always be limited by the application of the familiar methods of management.

The discussion of the corrective measures will follow in the same order as did the discussion of the defects. First, then, the limitation of unnecessary contacts with visitors, nurses and physicians.

1. a. Visiting hours for ward patients have been limited to five hours a week. The visitors are masked and gowned and by means of rope barriers are separated from the beds in each public ward so that they are least liable to contaminate the mothers or their bed units. It is admittedly a concession to popular opinion that visiting hours are as many as they are and are countenanced at all, even under these conditions.

b. Nurses are required to wear masks and gowns at all times while caring for infants in the nursery. Routine cultures are made of material from the throats of nurses who are about to come on duty in the nurseries. If dangerous organisms are found, the nurse is relieved of her duties. Complete studies are made to determine whether her infection is in any way a menace to the infants who have been under her care.

If so, the nursery affected is quarantined, and the infants in it are treated as indicated by the studies made.

c. A physician must wear mask, gown and sterile gloves on entrance to any nursery for newborn infants. He must examine the infant in the special examining room attached to every unit unless there is an emergency which takes him into the nursery proper. If the physician passes from one unit to another, he must change his mask, gown and gloves for every unit entered. House officers are assigned to individual nursery units and are not shifted unless they are ill or terminate their service in the nursery. This refinement should not be necessary if strict technic is observed. If they become ill, they are relieved of their duties and are studied to ascertain whether their illness will in any way affect the infants who have been under their care. If so, the nursery affected is quarantined, and the infants in it are treated accordingly.

---

[1] Weymuller, C. A.: Measures for the Protection of Newborn Infants, Child 5:215 (March) 1941.

d. Ward maids and cleaning women in the nurseries are subject to the same regulations as nurses and physicians and are rigidly supervised by both.

e. Every nursery unit has in its examining room complete medical equipment, so that no contamination can occur by way of stethoscopes, otoscopes or other instruments which might be brought in by the attending or house staffs.

f. All bedclothing, diapers and clothes for the infants in the nurseries are sterilized by autoclave. Each infant's supply for the day is stored in a shelf under his crib. Thus, only his own nurse comes in contact with his supplies. A further most practical refinement is the sterile packet devised by our nursing staff for the infant at bath time. This packet contains sterile cotton balls for laving the infant's eyes with normal saline solution, a sterile shirt, diaper and dress, and a sheet and blanket for the infant's bed. This is in sharp contrast with the usual practice of having a central supply room.

2. We have made our nursery units as small as our physical plant would permit. As can be seen from figure 1, each main unit consists of a room containing sixteen cribs, an adjoining but separate room for weighing and bathing, and an examining room partitioned off for the use of physicians. If we had complete freedom of action we should have the units contain 8 infants. (Although it will again be mentioned, it should be observed that each unit has a refrigerator for the storage of milk mixtures, a bottle warmer, a sterilizer and a scrub sink.) The cribs of each unit are arranged in two groups of eight and are never interchanged.

3. The measures taken to prevent the spread of infection from infant to infant through an intermediary are as follows:

a. The assignment of nurses caring for newborn infants has been changed so that one nurse cares for but 8 babies of full term and 1 premature baby. The nurse is assigned for complete care of these infants; that is, she takes them to their mothers to be nursed or gives them their milk mixtures or fluids, bathes them, weighs them and cares for them in every particular. This personal, individualized service permits the nurses to know in detail the condition of the mothers and babies in their charge. If they follow the required technic, they cannot transmit any infection beyond their group, much less beyond the ward of 16 in which they function. This is one of the greatest improvements which we have made and is, we believe, unique. Until war shortages forced a change we were able to function most satisfactorily. The circumstantial breech of this ideal setup caused us considerable difficulty which will later be described.

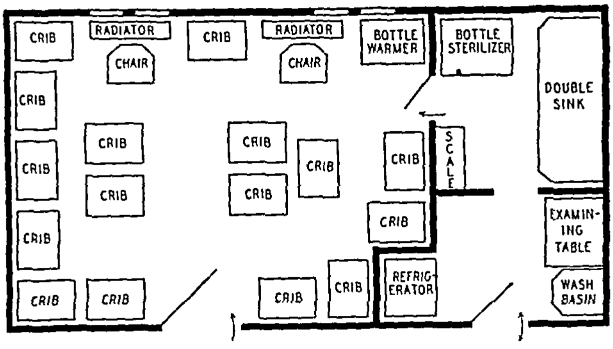

Fig. 1.—Typical nursery unit for newborn infants.

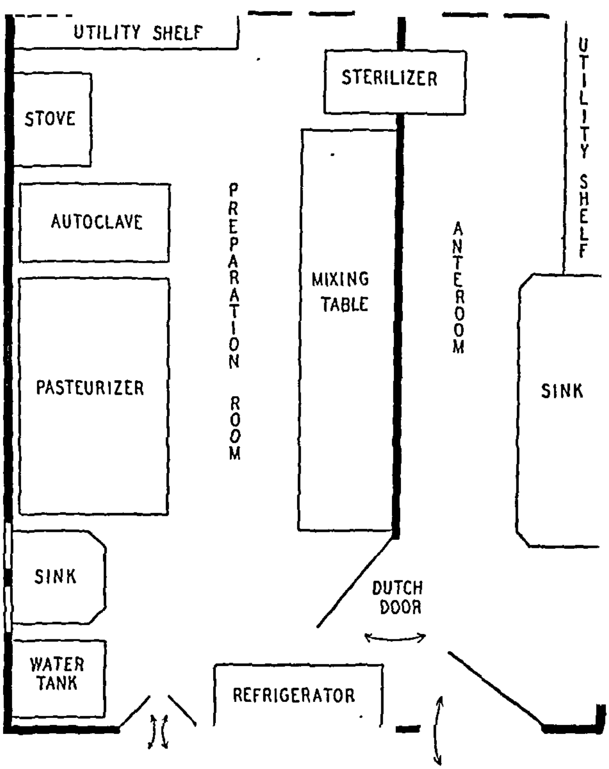

Fig. 2.—Present formula unit.

The formula room is in a section of the hospital entirely removed from the nurseries or sick patients. Ideally, we believe that it should adjoin the unit in the clean surgical division where sterile solutions and similar materials are prepared or, second best, perhaps the diet kitchens. The formula room is so arranged that contamination from outside the hospital or from any unit in the hospital is reduced to the minimum. All materials and utensils which enter the formula room pass through the sterilizer, which extends through the wall between it and the anteroom, or over the Dutch door (fig. 2). The sterilizer, of course, will destroy all contaminants. A special technic has been worked out to permit the use of the Dutch door and still avoid the introduction of contamination.

Once in the unit, these materials are made into milk mixtures according to formula, placed in sterile bottles, capped with sterile nipples and covered with sterile glass caps. All this is done by trained nurses in sterile gowns, masks and gloves. These nurses are carefully supervised and inspected and are relieved of duty immediately whenever they are ill. Their throats are cultured at the beginning of their term of duty in the formula room and subsequently whenever indicated. Although all these precautions are taken before and during preparation of mixtures, it is nevertheless considered that there might be contamination by air, hands or otherwise. Therefore the milk mixtures and other fluids are pasteurized at 140 to 160 F. for thirty minutes. Repeated cultures of mixtures so prepared have shown that they are sterile. If formulas were autoclaved after preparation in a clean formula room, the need for aseptic technic might be obviated. However, certain mixtures curdle when they are autoclaved and require buffering to counteract this.

All the bottles, nipples and utensils which return to the formula anteroom from any unit for infant or child care in the hospital, such as the nursery for newborn infants, the children's surgical ward or the children's medical ward, are washed and sterilized in the unit where they are used before they come to the anteroom. They are again cleansed and sterilized before they are delivered to the formula room proper.

When milk mixtures have been completely prepared, the bottles are passed through a window in the formula room and are then transported in a closed cart, used exclusively for sterile milk mixtures, to the unit where they are to be used. Each unit has its own refrigerator to receive these mixtures and materials.

d. A common utility room is not needed, because each unit has its bottle warmer, its sterilizer and scrub sink, and plenty of utensils. As all utensils are cleansed and sterilized before they leave the unit, contamination cannot be spread to other nursery units or to the formula room.

e. Proper isolation units are provided both for observation of suspected cases and for infants who are known to have transmissible diseases. The suspect nursery unit of eight or more cribs is located across the hall from the clean nurseries and is completely separated from them. It is equipped in the same way as are the larger nurseries (fig. 3). Infants who are suspected of harboring transmissible diseases are observed there until discharged from the hospital. This includes infants who have had numerous or loose stools. The nursing and medical personnel and the equipment of the intermediary isolation unit are complete and independent of all uncontaminated units. If infants prove to have true diarrhea, epidemic or not, they are transferred to the pediatric department ward, where rigid isolation technic is observed

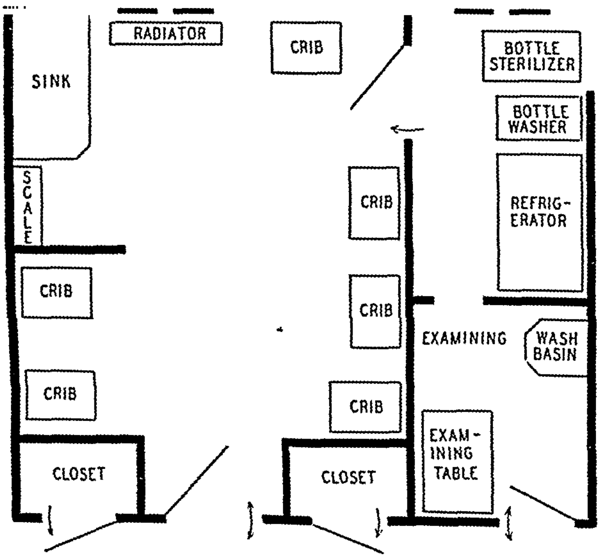

Fig. 3.—Suspect nursery unit.

Therefore, if any infant in any unit has infection the following steps are taken:

1. The affected infant is immediately isolated. For infections of any importance complete isolation is instituted at once.

Comparison of Three Routines for Care of the Skin of Newborn Infants

Method	Total Cases	Cases of Pyoderma	Incidence per Thousand Cases
A. 1930-1940 1. Isolation 2. Closure of nursery 3. Local treatment (various)	10,534	130	12.3%
B. 1940-1942 1. Inunction with 2% ung. hydr. am. 2. Isolation 3. Reinunction of contacts with 2% ung. hydr. am. 4. Closure of nursery 5. Local treatment with 5% sulfathiazole ung. (emulsion base)	3,064	35	11.0%
C. 1942-1946 1. Inunction with 15 Gm. 5% sulfathiazole ung. (emulsion base) 2. Isolation 3. Reinunction of contacts with 5% ung. sulfathiazole 4. Closure of nursery 5. Local treatment with 5% ung. sulfathiazole	8,727	8	0.9%

2. The unit from which this infant came is closed to further admissions until the hospital physicians feel certain that new cases will not develop.

3. The nursing and medical personnel of the unit involved observe the most meticular aseptic technic and carefully observe every exposed infant for the development of symptoms.

4. When a contaminated nursery has been emptied, it is thoroughly washed with soap and water and aired; it is not reopened for twenty-four hours after cleansing. All cribs and mattresses are specially treated.

PROPHYLAXIS OF PUSTULAR CUTANEOUS INFECTIONS

As we reported[2] in May of 1945, we had by that time anointed 3,205 infants just after birth with 15 Gm. of 5 per cent sulfathiazole in an emulsion ointment base, in an attempt to prevent pustular infection. If the infants were exposed, we reanointed them with this preparation, closed the nursery and treated any infant having pyoderma by evacuating pustules under 70 per cent alcohol; we then made frequent local applications of 5 per cent sulfathiazole water-soluble ointment.

The results have been excellent. From August 1942 to May 1946 there have been only 8 sporadic cases of pyoderma in 8,727 infants, without spread to neighboring infants in the same nursery or to those in adjacent nurseries. The blood sulfathiazole levels, blood counts and urinalyses were not significantly altered in a preliminary study.[1] Of the 8,727 infants who had had prophylactic inunction with 5 per cent sulfathiazole ointment in an emulsion base, 126 were readmitted for serious illnesses which required full dosages of sulfonamide compounds. One hundred and three were admitted once for heavy treatment with sulfonamide compounds; 15 infants had two such admissions; 6 had three; 1 infant had four, and 1 had five such admissions. In none of the 126 infants was there any evidence of sensitization to sulfonamide compounds.

---

[2] Weymuller, C. A., and Ittner, E. J.: Sulfathiazole Ointment for Prevention and Treatment of Pyodermas of Newborn Infants, Am. J. Dis. Child. 69: 283 (May) 1945.

SUMMARY

Section I describes the following measures employed since May 1937 at Long Island College Hospital for the protection of newborn infants:

1. Small nursery units were substituted for the customary large nurseries.

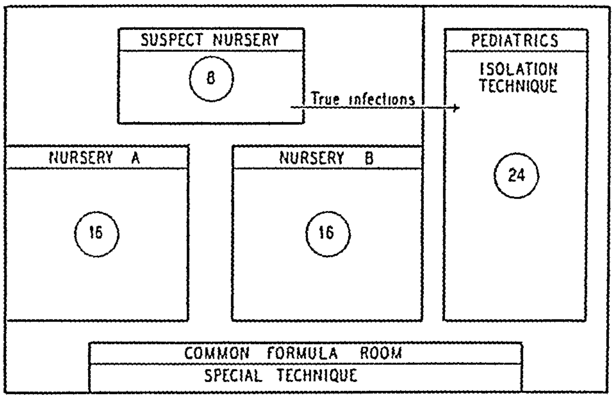

Fig. 4.—Setup in Long Island College Hospital for care of newborn infants. Because of a wartime shortage of nurses, nurses from A and B were caring for infants in suspect nursery.

2. All facilities required for care of newborn infants were duplicated in each nursery unit, a measure which eliminated the common utility room, the common linen store room, the common drug closet and the instruments used in common by the pediatricians and nurses as factors in spreading infection.

3. Nursing personnel was assigned to each nursery unit, so that absolute control of this element is secure. A common formula room was so constructed and managed that separate formula rooms for each nursery unit are unnecessary.

A brief report of the results of prophylaxis against pustular cutaneous infections is included.

II. Practical Experiences with Prophylaxis of Diarrhea: Management of a Diarrhea Epidemic

Following is a brief report of our practical experience with the measures instituted for the prophylaxis of diarrhea of the newborn and how we managed an epidemic of diarrhea which followed a compulsory failure to observe them. It is hoped that with the help of the diagrams presented the important points will impress themselves on the reader and so be of use in the protection of newborn infants from diarrhea.

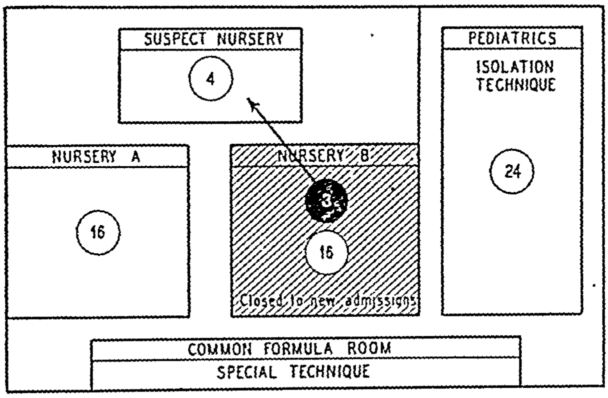

Fig. 5.—Situation on first day of diarrhea outbreak, Oct. 23, 1945.

First of all, we evolved our prophylactic program because a potentially tragic experience made us realize how vulnerable we were. From 1929 to 1937 we did not have any trouble from diarrhea, with all the gates open. Then a mother who had had Flexner dysentery at her sixth month of pregnancy (unreported to her physician) was delivered at Long Island College Hospital. On the seventh day her infant had many loose stools, was isolated and was successfully treated. Had that infant really had Flexner dysentery, which it fortunately did not have, the approximate contacts were 40 infants in four adjacent, unprotected nurseries, 25 patients in the children's surgical ward, 25 patients in the children's medical ward, the private patients and the entire medical nursing and service personnel. A good many more than 90 persons were in jeopardy, because we had a hospital setup like many another, which was entirely unsound for the management of enteric infection, whether specific or not. We escaped in this instance, but resolved not to tolerate the continuance of conditions which could repeat this hair-raising experience. Accordingly, our set-up was altered in the manner described in section I, at low cost and in an old hospital of rigid design.

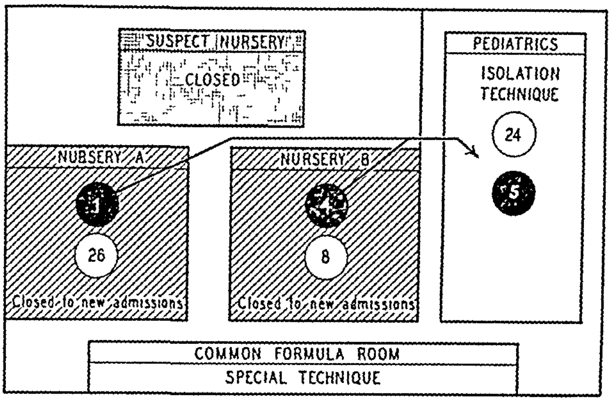

Fig. 6.—Diarrhea outbreak, six days after inception (October 29).

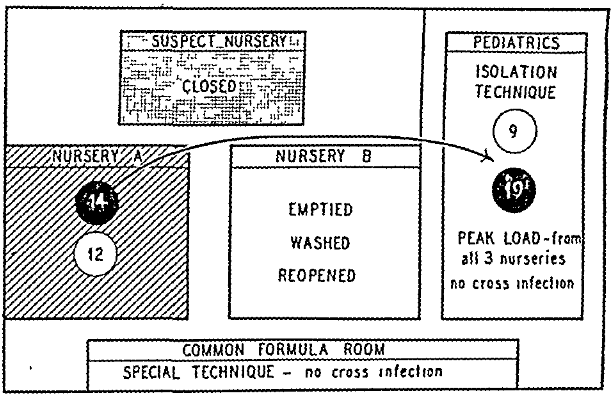

Fig. 7.—Diarrhea outbreak, seven to ten days after inception (October 30 to November 2).

We got along beautifully and soundly from May 1937 to October 1945 with our prophylactic technic. For months during the last years of the war we were so short of nurses that our technic was necessarily violated, and these errors caught up with us on October 23, 1945.

The day before the outbreak there were 40 infants in three of the nurseries: 16 in nursery A, 16 in B and 8 in the suspect nursery (fig. 4). None had diarrhea. All these infants and those in the twenty-four bed pediatric ward received formulas made in the common formula room under special technic.

Unfortunately, wartime shortages required the nurses in A and B nurseries to care for infants in the suspect nursery, thus converting the setup into a single nursery *completely* inadequate to protect against diarrhea, whether specific or nonspecific.

On the first day of what proved to be an epidemic (fig. 5) 3 infants who had moderately loose stools were transferred to the suspect nursery, and B nursery was closed to new admissions. Within six days (fig. 6) 3 more cases had developed in B nursery and 1 case in A nursery. Obviously, therefore, the personnel from A nursery had carried the contamination from the suspect nursery to complete the circle. Meanwhile, of course, the suspect nursery had been closed, since all infants with diarrhea had been transferred to the pediatric wards under strict isolation technic. By the sixth day of the epidemic a total of 5 infants had contracted diarrhea in a moderately severe form and had been transferred to the pediatric wards.

Fig 8 —Progress of diarrhea outbreak.

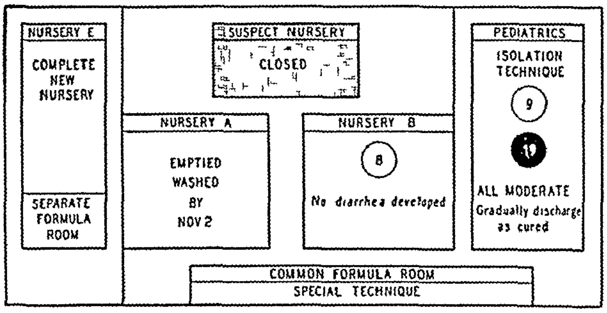

Fig. 9 —Diarrhea outbreak, eleventh day after inception (November 2)

It is to be noted that a common formula room was used for all units for infant care and that there were uncontaminated infants in the pediatric wards, in rooms adjacent to those in which there were patients with diarrhea. Even so, with enteric precautions, cross infections did not occur in the pediatric unit, or in any other unit of our hospital.

Immediately after the diarrhea epidemic began, the unit system was rigidly reestablished. Attending staff, house staff and nursing and service personnel were assigned either to clean or to contaminated units, never to both, and were not exchanged. Obviously, many institutions could not mobilize so large a personnel, and if technic is rigidly observed, this should not be necessary.

SECOND STAGE OF EPIDEMIC

From the seventh to the tenth day after onset, 14 more infants had acquired diarrhea and were transferred to the pediatric ward (fig. 7). The 12 remaining infants in the contaminated nursery A escaped entirely and were discharged at the usual time.

SPECIAL TECHNIQUE-no cross infection

Fig 10 —Conditions during final days of diarrhea epidemic

By the seventh day, the problem of the care of uncontaminated newly born infants had to be met. Accordingly, permission was given to clean up nursery B, staff it with an entirely new and independent crew and open it for admissions. Eight infants were gradually admitted into this unit and were maintained without cross infection until their customary day of discharge. It should be noted again that the formula room which serviced the reopened nursery B also served contaminated nursery A, the 19 infants with diarrhea on the pediatric wards as well as the uncontaminated infants on the pediatric ward. This was done without cross infection; a real proof that this system is a good sound one, if similarly administered.

THIRD STAGE OF EPIDEMIC

On the eleventh day of the epidemic it was recommended by the New York Health Department (fig. 8) that a new and independent nursery, complete with formula room, be set up in another portion of the hospital. This nursery cared for 16 uncontaminated infants during the last days of the epidemic, without cross infection, just as was true of clean nursery B. However, nursery B, though just as effective, was adjacent to the contaminated nursery and was serviced by the common formula room. The point is worth reiteration that if facilities for the establishment of a new nursery complete with formula room cannot be produced, completely effective protection may still be accomplished by capable administrators, as we have hereby proved (fig. 9).

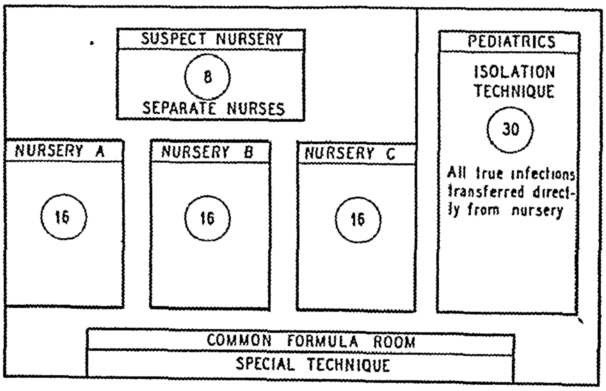

Fig 11 —Present setup at Long Island College Hospital.

FOURTH STAGE OF EPIDEMIC

As was noted, new nursery E cared for and discharged 16 infants without disturbance; nursery B, adjacent to contaminated nurseries, remained open successfully throughout the epidemic to receive uncontaminated newborn infants. Soon nursery A was reopened to new admissions without cross infection. The 19 affected infants in the pediatric wards recovered from diarrhea. Those infants adjacent to them on the pediatric wards did not acquire cross infection (fig. 10). A common formula room was used for all infants in the hospital, sick or well, except those in nursery E, the new, independent unit.

CONCLUSION OF EPIDEMIC

From the last day of the epidemic to date we have reestablished our nurseries on a unit system (fig. 11), and if nursing shortage again forces a change our only concession can be to reduce the patient load in one clean nursery. For example, nurses of nursery B might be assigned to the care of the suspected nursery. Admittedly, contamination from other nurseries which has been brought to the suspect nursery might thus be carried to nursery B. However, with proper technic it will stop there. Thereby the remaining nurseries will be protected and at least one completely clean unit will be available.

SUMMARY

Because of nursing shortages the effective prophylactic technic employed from 1937 to 1944 could not be observed. An outbreak of diarrhea in October 1945 passed through three nurseries which error had converted into one nursery and affected 19 infants. These infants all recovered from the diarrhea.

The progress from unit to unit is portrayed in the diagrams.

It was proved (1) that a common formula room for all hospitalized infants, sick or well, may be successfully used without cross infection in the hands of meticulously careful administrators; (2) that a clean nursery may be operated immediately adjacent to a unit contaminated with diarrhea without cross infection, if our technic is meticulously observed, and (3) that, as is generally conceded, an entirely new unit, complete with formula room and independent personnel, may be operated without cross infection. These measures have proved effective, practical of operation and at a cost level within the means of all who might be entrusted with such an important responsibility.

ABSTRACT OF DISCUSSION

Dr. Francis Scott Smyth, San Francisco: I think Dr. Weymuller's paper is most appropriate for those who are contemplating new building programs. Pediatricians must be on constant vigilance to keep up technics. Modern obstetrics demands that mothers come to the hospital for delivery, but I have a growing suspicion that the newly born infant would do better in the home. It seems to me that in many places the newly born infant is treated as on an assembly line, and it has been my observation that if one wishes to detect the nursing shortage, for example, the place to detect it is in the nursery. I should like to have had Dr. Weymuller discuss the use of propylene glycol or aerosol treatment. We are in the process of designing, we hope, a fine nursery for the future. At present I envy him with his apparent extra space where he can shift from nursery to nursery without any difficulty. The hospitals have been so crowded here in this city that I think we too are at the present time on rather thin ice when it comes to the danger of epidemic infection.

MODERN TREATMENT OF CHRONIC SINUSITIS

LELAND G. HUNNICUTT, M.D.
Pasadena, Calif.

By modern treatment of chronic sinusitis is meant the current treatment, whether it is old or new. To discover the source of the current treatment it is necessary to examine not only the work of the present generation but that of generations of the past.

In reviewing the literature, it was found that most of the present methods of arriving at a diagnosis of chronic sinusitis and the fundamentals of surgical procedures were in Dr. Hajek's book of 1898. In the foreword of the last edition, published in 1926, Heitger and Hansel, the translators, stated: "The first edition, published in 1898, placed anatomy, pathology and therapeusis of suppurative affections of the nasal accessory sinuses, for the first time on a solid foundation. In subsequent editions, a most significant and impressive feature is that Dr. Hajek found it unnecessary to retract or modify a single basic principle originally presented."

Since Hajek's time there have been improvements in surgical and in diagnostic procedures, but the greatest advance has been a better understanding of the physiology of the nasal mucous membrane. Having in mind what the normal nose is like, one can direct the treatment toward reestablishing this healthy state. This normal, healthy state means adequate aeration and drainage of the sinuses. To carry away foreign material, a tough mucous blanket propelled by cilia moves toward the nasopharynx. In planning treatment of chronic sinusitis, it is of great importance not to do anything which might permanently injure this mechanism of nasal cleansing. Medicaments must not have irritating chemicals. The p_H must be compatible with ciliary action. Structures necessary for humidifying and directing air currents should not be removed by surgical treatment, which must be planned in such a way that it does not destroy the glands so necessary for the maintenance of the mucous blanket protecting the cilia. An exception to this is when the membrane is so diseased it cannot recover.

AID FROM THE INTERNIST AND THE PEDIATRICIAN

The internist can help by carefully eliminating causes of the symptoms of chronic sinusitis, other than local conditions in the nose. His history and physical examination may show that a person has glandular dyscrasia and is apt to have disturbances of the mucous membrane. A dietary deficiency, including deficiency of vitamins and minerals, or inability to handle certain foods may cause a reflex upset in the nose. Certain habits, such as late hours, smoking, alcohol, excessive eating and worry, may produce congestion of the nasal membranes with the attendant lowering of resistance and secondary infection of the sinuses. The internist should be critical of the rhinologist's medication for the nose, as it may cause a chronic congestion and secondary effects.

The pediatrician can help the rhinologist by eliminating the factor of allergy and the overuse of nasal medication. The dietary problem is as important as in the adult, but this has usually been disposed of in the pediatrician's routine care of the child. Not infrequently the correction of some of these conditions by the internist or the pediatrician will clear up what is simulating a chronic sinusitis.

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

Having received this help from the physicians who refer the patients to us, we rhinologists then have a definite obligation to them. We must report to the physicians the involvement of the sinuses, the treatment anticipated and the prognosis. If the condition is serious enough to warrant the consultation, then we must make every effort to clear up the complaint.

DECISION AS TO TREATMENT

The rhinologist, like the tracker of wild animals, is trained to observe the signs which have significance in leading to the "prey"—in this case, to the chronic sinusitis. Often there is a history of excessive blowing of the nose and overmedication. If so, the patient cannot be properly evaluated until he has gone for a period of about four days without nose blowing and nasal medication. After about four days, the nasal mucous membranes will have a chance to return to normal as much as is possible and a better evaluation can be made. Since the patient is usually miserable because of nasal congestion and accumulation, a mild sedation may be used at bedtime. By the end of four days, the congestion is less and the secretion has been retrained to go posteriorly, the normal direction.

A roentgenogram is ordered at the time of the first visit, and at the second visit a rather complete evaluation of the chronic sinusitis can be made. The roentgenograms must be taken in the proper positions to determine the degree of disease in all sinuses. Complete roentgenologic interpretation is sometimes lacking until involved sinuses are irrigated. With these data at hand, usually the treatment can be outlined. The roentgenograms alone may indicate the need for surgical intervention; for instance, when they disclose chronic frontal sinusitis with osteomyelitis.

Inspection of the nose includes the search for any obstruction which would prevent proper flow of air or interfere with drainage of the sinuses. Obstructions may be from a deviated septum, a large turbinate or polyps. Correction of these may be necessary for reestablishing normal flow of air and drainage. Inspection is continued, an attempt being made to follow leads, as indicated by inflamed areas of mucous membrane and pus, to sinuses which are involved. The roentgenogram helps in looking for these leads. The nasopharyngoscope and the nasopharyngeal mirror, if used frequently, are good aids in noting anatomic and pathologic abnormalities. Repeated examinations are often necessary to discover pus coming from the sinuses draining into the middle meatus.

Bacteriologic and cytologic studies are made from the nasal passage as well as for the sinus cavities. The finding of eosinophils, especially if they are associated with swelling of the mucous membrane and polyps, means that the underlying allergy must be treated. Not infrequently, control of allergy means a clearing up of the chronic sinusitis because adequate drainage and aeration are reestablished. Diagnostic washings should always be done in the maxillary and sphenoid sinuses. An attempt should be made to wash the frontal sinus, if it appears to be infected.

NONSURGICAL TREATMENT

The treatment of chronic sinusitis in children is usually nonsurgical. Removal of infected tonsils and adenoids may eliminate frequent infections which keep up the sinusitis. When pus stagnates along the floor of the nose, removal of it by spot suction will permit the reestablishment of movement of the mucous blanket and facilitate drainage from the sinuses. Spot suction in the upper recess of the middle meatus has a similar beneficial effect on the ethmoidal cells.

Gentle nasal irrigation, with warm solution of sodium chloride and sodium bicarbonate, after general shrinkage removes excess mucus and pus and again permits a more efficient mucous blanket to function. This is of great value, especially for combined allergy and chronic sinusitis in children. Irrigation of the maxillary sinus by way of the normal ostium can frequently be accomplished in children. This should be done whenever possible, as it speeds up the clearing of the infection.

Local use of sulfonamide compounds and of penicillin is of questionable value for the chronic infection but of value for the acute exacerbation when the new pathogen is sensitive to the chemotherapeutic agent. The same can be said for administration of sulfonamide drugs by mouth and of penicillin hypodermically. Local use of a sulfonamide compound is of much value when it is lightly applied to a sinus cavity after removal of the lining in that it keeps down infection for a short time while the granulations are starting. Penicillin given hypodermically before and after radical operation on the sinuses is also a valuable aid in keeping down postoperative secondary infection.

Bacterial filtrates in the nose and sinuses are not as enthusiastically used as in the past, but there are times when they seem to be of value. In trying to clear up a chronic infection in the sphenoid sinus without surgical intervention when irrigations have been unsuccessful, it is worth while to instill an autogenous bacterial filtrate. Vaccines have apparently fallen into disrepute; in my experience, they have not been of value. Roentgenologic treatment of chronic sinusitis has proved of no help.

SURGICAL TREATMENT

Surgical treatment is directed toward improving ventilation and drainage of the sinuses and removal of diseased tissue. In examination of sinus linings removed in past years, rarely is chronically infected tissue found which is not capable of becoming a useful membrane if present knowledge of treatment is applied. The majority of the specimens show eosinophils, plasma cells and edema; they rarely show degenerative changes to the extent of being irreversible. This story of the past should be borne in mind while the present surgical procedures are considered.

Nasal Cavity.—A submucous resection of the septum should be done if it obstructs. Polyps should be removed, as little damage as possible being done to normal structures. Refraction of the middle turbinate should be done if the middle meatus has inadequate space. Crushing of the middle turbinate may be necessary if it is enlarged because of a turbinal cell.

Maxillary Sinus.—After repeated irrigations of the maxillary sinus, whether by the natural ostium or by puncture, if the infection continues an adequate window opening is made in the inferior meatus. The normal ostium, which may have been partly blocked by edematous mucous membrane, now has a chance to return to normal and function once more. Too large an opening may cause changes in the sinus lining, according to Hilding's observations, which are not conducive to a healthy state. If there is a polypoid lining, there is a greater chance that the window opening will not suffice and that the lining will have to be removed. This is done if suppuration continues.

A maxillary sinusitis of dental origin which has foul pus usually necessitates removal of the lining. Several irrigations may temporarily clear it up but, with a new cold, it usually forms the foul pus again. The infected bone at the site of the old apical abscess seems to keep up the infection of the lining. Curetting out the infected bone and closure of a fistula are necessary.

Ethmoid Sinus.—Infection in the ethmoidal sinuses usually clears up without an ethmoidectomy if all infection is eliminated in the maxillary and frontal sinuses. However, if a careful follow-up is not possible after the maxillary sinus has been cleaned, it is often better to do an ethmoidectomy. Care should be taken to leave the middle turbinate intact.

Sphenoid Sinus.—Chronic infection in the sphenoid sinus usually clears with conservative treatment, but if repeated washings fail, then there should be conservative surgical intervention. The normal ostium may be enlarged or an opening made adjacent to the normal ostium which will permit the thickened mucous membrane that may be interfering with drainage to return to normal. Removal of the anterior wall and floor and stripping out the lining of the sphenoid are rarely necessary.

Frontal Sinus.—The frontal sinus usually responds to repeated irrigations. It may be necessary to remove one or two anterior ethmoidal cells, which make up the nasofrontal duct, for easy entry into the frontal sinus. This converts the duct into a frontal ostium. Even though the irrigator passes into the frontal sinus, there may be polypoid mucous membrane which is pushed aside only to block the ostium again after the irrigator is removed. It is necessary to create a clean, open middle meatus if the frontal sinus is to be given a proper chance to clear up. If conservative treatment does not eliminate suppuration, some form of the Lynch operation is done. If infection persists or there is osteomyelitis of the anterior plate, more radical surgical treatment may be necessary.

SUMMARY

A more adequate knowledge of the physiology of the nose and sinuses permits an approach to treatment with a definte goal in mind, that is, restoration of the nose to normal functioning and freeing the sinuses from disease.

The internist and the pediatrician can help the rhinologist by eliminating and treating conditions which contribute to chronic sinusitis.

Modern nonsurgical treatment includes so much more than in past years that much less surgical treatment of the sinuses is now necessary.

The recuperative powers of the mucous membrane of the sinuses are greater than was once supposed; hence its removal is less frequently done.

Careful planning of the treatment, whether it be nonsurgical or surgical, will result in many more cures of chronic sinusitis.

ABSTRACT OF DISCUSSION

Dr. Lewis F. Morrison, San Francisco: I do not come up here with as much pleasure as I did yesterday. I read the paper twice, and I did not quite believe it, for the reason that it is no example of the man's ability. It was a poor subject. Perhaps he was persuaded to take it against his inclination. He is a man of great ability; he has done a great deal, and he has much to offer us. It is a good summary, but there is not time now to go into the various small points, and I do not think that he would welcome my picking out one or two small points to discuss. The only thing which I want to bring forward to you is that this is no representation of what Dr. Hunnicutt really is, and the experimental work which he has done and the hours which he has spent in the laboratory. If you can get him off in a corner and talk to him, you will really find out what he is.

Dr. Robert C. McNaught, San Francisco: The title of the paper implies chronic sinus infection, which is now recognized as a comparatively rare condition in pure form. Most of what is called chronic sinusitis is not chronic infection but subacute infection prolonged in a person whose membranes react allergically. Its treatment by the so-called conservative methods is as surely doomed to failure as by the radical methods until something more basic is known about control of the allergic reaction. Dr. Hunnicutt attempted to cover only treatment. Mention was made of diagnostic methods, but the point of my remarks is that these should be emphasized because chronic sinusitis, if pure infection in the sinuses is meant, is a rare condition, and that most of the time should be spent on an accurate differential diagnosis so that the part which allergic reaction in the patient plays in the chronicity of his particular symptoms may be known. This diagnosis includes a careful history and, more important, a proper interpretation of that history. Roentgenologic examination, as mentioned by Dr. Hunnicutt, is only of accessory value. Bacteriologic studies are practically of no value. The diagnosis should be based on frequent and repeated lavage of the antrum, with study of the secretions obtained—microscopic study—for the presence of eosinophils or polymorphonuclear cells. At the time of the puncture note should be taken of the capacity of the sinus, which provides information as to the thickness of its lining. It also provides information about the patency of the ostium. All such information is necessary for planning of the treatment to be employed. Dr. Hunnicutt did not mention the Proetz method of irrigation, which I think is of distinct value in children. I am a little surprised, in view of the current talk about p_H, that he did mention the use of sodium bicarbonate in a nasal douche. The p_H, of course, brings up the question of nose drops. Nose drops have no place in treatment of any chronic nasal condition, whether it be chronic infection of the sinuses or one of the allergic states, because any transient benefits which may result are far outweighed in the long run by the secondary effects. Therefore p_H does not come into the question of chronic disease of the sinuses. As brought out by Dr. Hunnicutt, the modern trend in the treatment of chronic sinusitis is toward conservation of structure and function. He does not advocate conservatism in the sense of nonintervention.

Dr. Leland Hunnicutt, Pasadena, Calif.: I appreciate both of the discussions. In answer to Dr. Morrison's remarks, the subject assigned called for a presentation of the modern treatment of chronic sinusitis. An outline was prepared based on that which my colleagues and I use at the Los Angeles General Hospital for teaching the residents and as a guide for the teaching staff. Dr. McNaught criticized the use of sodium chloride and sodium bicarbonate for nasal irrigation because of improper p_H. This solution is used as an office treatment when it is desirable to get rid of thick secretion in order to make the nose more comfortable and allow the mucous membrane to function better. This is not done as a daily procedure. I still have great respect for the proper p_H of the solutions to be used in the nose.

OTIC COMPLICATIONS OF STREPTOMYCIN THERAPY

A Preliminary Report

EDMUND P. FOWLER Jr., M.D.
and
EWING SELIGMAN, M.D.
New York

Neurotoxic symptoms involving the vestibular and auditory systems may occur following streptomycin therapy. Hinshaw and Feldman[1] mentioned 1 case of transient deafness and 3 cases of apparent disturbances of vestibular function when large doses of streptomycin were administered over long periods of time. Molitor and his co-workers[2] found signs of pronounced disturbances of vestibular function in dogs after extremely large doses of the drug (ten to twenty times the usual human dose per kilogram of body weight). Mushett and Martland[3] did not observe pathologic changes in the central nervous systems of these dogs. The first specialized report of aural complications in human beings has been made by Brown and Hinshaw.[4]

Our series of 81 cases from a large military hospital consists of patients who received streptomycin during the period November 1945 to August 1946. During this same period approximately 80 other patients received the drug in this hospital. The particular patients in our group were used because of their availability at the time of our visits to the hospital. However, all patients on streptomycin therapy who complained of dizziness, tinnitus or impaired hearing were included. For this reason the patients showing complications can be considered the total number of such patients out of approximately 160 patients treated with streptomycin.

Patients with known disease of the ear were excluded from our statistics. Among these there were 2 cases of acute otitis media, 1 case of chronic otitis media, 1 case of brain abscess secondary to mastoiditis and 1 case of otosclerosis. There were 80 men and 1 woman; all were healthy adults before their present illness. Their ages ranged from 19 to 51; 64 per cent were in the age 20 to 29 group and 29.2 per cent were from 30 to 59. The diseases for which treatment was being given were osteomyelitis (71.6 per cent), and urinary infections (16.3 per cent); there was also 1 case of each of the following conditions: infection of soft parts, infected burns, subacute bacterial endocarditis, undulant fever and osteomyelitis and urinary infection in the same patient. The dosage was usually 3 Gm. streptomycin (3 million units) a day given intramuscularly 0.5 Gm. every four hours. The total dosage was small compared to that necessary for the treatment of tuberculosis. Nineteen patients received 20 to 29 Gm.; 16, 10 to 19 Gm.; 15, 30 to 39 Gm.; 14, 40 to 49 Gm.; 4, less than 10 Gm., and 1 a total of 141 Gm. Twelve patients were given more than one course.

The interval between the cessation of therapy and our initial examination varied from one day to six months. Incidentally, all patients had received penicillin therapy before treatment with streptomycin was started. Only 15 of the patients in the series were examined both before and after streptomycin therapy. Their initial poststreptomycin examination was made within one week after discontinuation of the treatment.

The initial examination consisted of an otic history, otoscopic examination, audiogram for air conduction and Kobrak caloric test, in the order named. For the Kobrak caloric test, the head was turned to the side, the external canal straightened by tension on the auricle and a medicine dropper of ice water at approximately 7 C. instilled. The head was turned on the other side after about five seconds to allow the water to escape, and then another dropperful was instilled and allowed to escape. The latency of onset of nystagmus was computed from the time of instillation of the first dropperful of water. If there was no response to this stimulus, several more droppersful were used. If there was still no response, ice water was run in with an irrigating can for five minutes or until a response was noted. A latency of more than forty seconds was arbitrarily designated as "delayed." This test is not quantitative; it merely detects labyrinths with serious hypofunction. It is planned to do accurate quantitative tests according to the technic of Fitzgerald, Cawthorne and Hallpike[5] in the future.

Table 1.—*Results of Examination of Eighty-One Patients After Streptomycin Therapy at Halloran General Hospital*

Audiometric			Vestibular		
	No.	%		No	%
Normal	26	32.1	Normal	65	80.2
Low tone loss (256 and 512)	1	1.2	Delay	13	16.0
High tone loss (2,896, 4,096 and 8,192)	42	51.8	Absent *	3	3.7
High and low tone loss	11	13.6			
All tone loss *	1	1.2			

* These figures probably represent all such cases out of the entire group of approximately 160 patients being treated with streptomycin at the same hospital during our study. All the other losses shown in this table are probably not due to streptomycin therapy. Audiometric losses are those commonly found in wounded military personnel. The delayed vestibular response occasionally occurs in normal persons.

The majority of these patients were confined to bed and had to be examined in the wards. It was impossible to control the outside noises under these conditions. Most noticeable was low tone interference due to the almost constant motor noises from airplanes, military vehicles and grass cutters. The overall ambient noise level varied considerably from time to time. The range was 35 to 65 decibels, the average close to 45 decibels. The 15 patients examined before as well as after streptomycin therapy were examined in the audiometric room of the Ear, Nose and Throat clinic. This room is not soundproofed and is exposed to much the same outside interference as the wards. For this reason a threshold change below a level of 30 decibels was considered unreliable.

Summaries of the results of these examinations are shown in table 1. Of 81 patients examined after streptomycin therapy, 53 (65 per cent) showed a high tone loss. Of these, 11 (13.6 per cent) showed a low

tone loss in addition to the high tone loss. None of the low tone losses were greater than 35 decibels, and losses of this magnitude are always subject to question unless the tests have been performed in a soundproofed room. The high tone losses ranged from 30 to 100 decibels in the 2,896, 4,096 and 8,192 frequencies, and we believe they were due to acoustic trauma. Hoople has found similar losses in 1,000 wounded military personnel.[6] Many patients showing appreciable high tone loss gave a history of shell burst nearby. These inferences are supported by the fact that the 15 patients examined before streptomycin therapy also showed similar high tone losses (12, or 80 per cent, showed high tone loss before the drug was given). One patient showed pronounced loss for all tones after administration of the drug. This was undoubtedly due to the streptomycin therapy, because his prestreptomycin audiogram showed only a slight high tone loss at a frequency of 8,192.

Caloric stimulation after streptomycin therapy revealed a normal response in 65 (80.2 per cent) patients. There was a delay in one or both sides in 13 (16.0 per cent). In 3 (3.7 per cent) there was absence of nystagmus after irrigation for five minutes with ice water. The significance of delay is difficult to evaluate with the test employed. Of the 15 patients examined before and after therapy 1 showed delay before and the same patient as well as 1 other showed delay after therapy. There is always some question as to whether a slightly subnormal response is significant.

None of the 3 patients lacking vestibular response to ice water was examined before streptomycin therapy. The observations in these patients are summarized in table 2. The vertigo in these patients reached a peak during or shortly after therapy and has shown a steady decrease ever since. All 3 are at present up and around, and the vertigo is not in itself incapacitating. Two of these patients had a persistently negative and 1 a persistently positive Romberg sign. Two of these patients have shown signs of recovery of vestibular response. One began to show recovery two months after the cessation of therapy; two weeks later responses to caloric tests and postrotational nystagmus were nearly normal. The other showed a first degree nystagmus after three minutes of irrigation with ice water two months after the streptomycin therapy was discontinued.

It should be reemphasized that the 4 patients who showed definite toxicity as a result of streptomycin therapy are probably all there were in the entire group of approximately 160 patients who were being treated with the drug during the same period in the Halloran General Hospital. Thus these cases would constitute less than 3 per cent of our series. Three of these patients complained of vertigo spontaneously before examination. In addition, 2 other patients complained of dizziness. One of these had received only 12 Gm. of streptomycin, and he did not complain until four days after the cessation of therapy. This was the day he read a newspaper article on the subject. The only observation in this patient was a high tone loss of

---

[6] Hoople, G.: Tr. Am. Otol. Soc., 1946, to be published.

40 decibels at a frequency of 8,192. He had a normal response to the Kobrak caloric test. The other patient had had dizziness on numerous occasions during febrile illnesses. She had been hard of hearing since late childhood. She noticed the symptom when she sat up for the first time after the cessation of therapy. There was considerable general weakness, and her debility at the time of the examination could easily account for some dizziness. Her Romberg sign was inconclusive. Her response to the Kobrak caloric test was normal. Her audiogram showed a decided loss for all tones. There was no prestreptomycin audiogram. She was not included in the statistics for this study because of the strong probability that she had previous disease of the ear (otosclerosis).

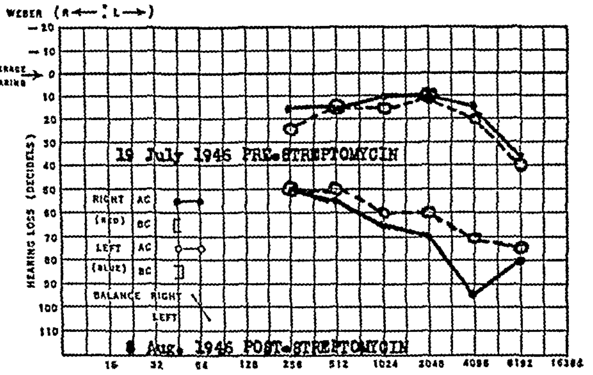
The streptomycin administered to 2 of the 3 patients lacking vestibular response bore the same manufacturer's lot number. In these 2 patients the first symptoms appeared during the first three days after the change from the drug bearing one lot number to that with another. In the third patient the manufacturer's lot number has not been identified. The patient showing impairment of hearing was treated with streptomycin from only one lot. Many other patients received streptomycin from these same lots in equal dosage without evidence of toxicity. If the cause were an excessive amount of an unknown impurity in certain lots of the drug, one would expect that more patients receiving that with the same lot number would be affected. If the toxicity were simply due to the amount of streptomycin given, one would expect to see symptoms in patients receiving the largest doses. The patient receiving the largest dose in our series (141 Gm.) had a response to the Kobrak test delayed for one and one half minutes eight days after the cessation of therapy; three months after this there was no delay. He did not have symptoms of toxicity at any time. His poststreptomycin audiogram showed nothing unusual. Certainly there must be an individual suspectibility to the toxic effects of the drug. It is an interesting fact that in both man and experimental animals otic symptoms have been caused by high potency streptomycin in lots derived from crystalline material and symptoms were not produced by some lots of the drug which were of extremely low potency.

REPORT OF CASES

Case 1.—A man aged 24 was given streptomycin because of chronic pyelonephritis. His prestreptomycin response to the Kobrak caloric test was normal. His prestreptomycin audiogram (see the accompanying chart) was normal except for a high tone loss at 8,192 frequencies. He received 3 Gm. of the drug a day for five days. His first poststreptomycin audiogram was made three days after the cessation of therapy and showed decided loss of hearing for all tones. Two weeks later this loss had become worse. Four weeks later it had lessened to a level better than that of the first poststreptomycin audiogram. He had not complained of deafness or vertigo; however, on questioning he stated that he had noticed a slight impairment of hearing after one or two days of treatment, but that it had not been troublesome. He had also noticed a slight bilateral hissing tinnitus. He had had similar symptoms nine years before when he started antisyphilitic treatments and since then had noticed some impairment of hearing from time to time. His father had been deaf as long as the patient could remember. The patient was unintelligent and uncooperative during the examination, but the differences between the prestreptomycin and the poststreptomycin audiograms are too great to be explained by this (table 3). He had a loss of bone conduction which would indicate a nerve type deafness. He was transferred to another hospital after the audiogram of Aug. 20, 1946. The drug used was Merck lot 396.

Case 2.—A woman aged 26 was under treatment for an infected abdominal wound. She received two courses of streptomycin therapy. The first was from April 25 to May 5, 1946 on a dosage of 3 Gm. a day. There were no symptoms of otic toxicity during this time. The drug used was Pfizer lot 461.[7] She was started on a second course of treatment with Merck lot 398 on June 10, 1946. The same day she began complaining of subjective vertigo. This consisted of a sensation of turning in bed. She was allowed to be up during the course, and the symptom became somewhat worse when she was upright. The course was terminated early because of this symptom. The initial otologic examination was done on June 19, 1946. The audiogram showed a high tone loss at frequencies of 4,096 and 8,192 bilaterally. The Romberg sign was positive, the patient falling to the right. There was a lack of response to irrigation of both canals with ice water for five minutes. This test was repeated on Aug. 8, 1946 with the same response. On August 20 she showed slight response to the instillation of water at 44 C. and to rotation. These responses were increased on Sept. 3, 1946 almost to the normal level. Her vertigo is at present not incapacitating.

Case 3.—A man aged 22 had peritonitis following a ruptured appendix. On June 22, 1946 he was started on streptomycin therapy and received 3.5 Gm. a day until July 6, 1946. The manufacturer's lot numbers of the drug have not been identified. About June 29 he began to complain of objective vertigo increased by shifting his gaze. The room seemed to turn first one way and then the other. This symptom remained the same until he was allowed out of bed; since then it has steadily lessened. He remained in bed during the entire course of treatment. He did not have deafness or tinnitus. Examination on Aug. 20, 1946 showed a normal audiogram. There was no spontaneous nystagmus. The Romberg sign was normal. Irrigation of both canals with ice water for five minutes did not produce nystagmus. Rotation ten times in twenty seconds failed to produce a response. On Aug. 21, 1946 there was no response to the instillation of water for five minutes at 30 C. and 44 C. and to rotation ten times in ten seconds. On Sept. 9, 1946 there was a 1 degree nystagmus of twenty seconds duration after irrigation of the auditory canals with ice water for three minutes. At present he has been discharged from the hospital and is able to work.



Audiometric examination (case 1) before and after streptomycin therapy.

Case 4.—A 32 year old man with subacute bacterial endocarditis started treatment on May 8, 1946 with a dosage of 3 Gm. streptomycin a day from Pfizer lot 461. Simultaneously he received penicillin 100,000 units every four hours. On May 23, 1946 a generalized cutaneous rash developed. On May 25 the administration of penicillin was discontinued and the type of streptomycin changed to Merck lot 398. Treatment was discontinued on May 28, 1946. On the same day the patient began to complain of dizziness. His first otologic examination was on May 29, 1946. He had moderate bilateral hyperostosis of the auditory canal, so irrigation was performed for five minutes with ice water through a ureteral catheter. There was no nystagmus. This procedure was repeated on Aug. 8 and 20, 1946 with the same results. His audiogram was normal. Subjectively his vertigo has shown a steady decrease. He is up and around at present, and this symptom is not incapacitating.

---

[7] Chas. Pfizer & Company, Inc.

CASE 5.—S. B., the first patient treated with streptomycin at Presbyterian Hospital, reported through the courtesy of Dr. Alvan Barach, was a man aged 38 with pulmonary tuberculosis. He was started on a streptomycin dosage of 250,000 units every four hours (Merck lot 280) on July 17, 1945. After four doses his temperature rose to 101 F., and during his daily trip to the bathroom he suddenly lost consciousness. This lasted only a few minutes, and he felt no ill effects the following day. Administration of the drug was discontinued, and three days later, on July 20, 1945 he was started on Merck lot 284 with the same dosage. During the next three days he experienced increasing generalized aching and joint pains. This became so severe that treatment was again discontinued on July 23, 1945. On July 25 the drug was resumed and a third lot, Merck 303, was used in the same dosage. There were no signs of toxicity until August 7, two weeks after the initiation of treatment. He began complaining of vertigo and impaired muscular coordination. On this account treatment was stopped Aug. 11, 1945. His vertigo showed a gradual steady decrease. On Jan. 21, 1946 a caloric test was performed which showed a lack of response to ice water instilled for five minutes bilaterally. On Sept. 3, 1946 there was no response to water at 30 and 44 C. instilled for 40 seconds bilaterally. At present vertigo has almost completely disappeared. He has not complained of impaired hearing. The results of audiograms at the time of the caloric tests are shown in table 4. At present there is no apparent hearing loss with normal conversation. An audiogram was not made before streptomycin therapy began.

CASE 6.—W. P., a patient in Babies Hospital reported through the courtesy of Dr. H. R. Craig, was a boy aged 5 with a diagnosis of tuberculous meningitis. On May 4, 1946 he was started on streptomycin therapy, 50,000 units given intrathecally twice a day. This was discontinued on May 25. On May 14 a spontaneous vertical nystagmus had been noted. On May 27 progressive bilateral loss of hearing was observed. From June 4 to 20, 1946 he received 160,000 units of the drug every three hours intramuscularly and 100,000 units a day intrathecally. On July 7, 1946 there was no nystagmus after irrigation with ice water bilaterally. It was believed that there was complete deafness at this time. On July 16, 1946 he was discharged from the hospital improved, and with a normal spinal fluid. On Sept. 1, 1946 he was readmitted because of signs of exacerbation of the meningitis. The deafness was still complete. On Sept. 5, 1946 he was started on a streptomycin dosage of 120,000 units every three hours given intramuscularly and 100,000 units a day intrathecally. He did not complain of vertigo but was still totally deaf. At the time of his death Dec. 1, 1946. The lot numbers of the drug used have not been identified.

COMMENT

We have observed several other cases of otic complications following streptomycin therapy through the courtesy of Dr. H. C. Hinshaw and Dr. H. A. Brown of the Mayo Clinic and Dr. Walsh McDermott of the New York Hospital. It is evident that a high incidence of vestibular disturbance and a sizeable number of cases of deafness, either transitory or permanent, will occur with the use of streptomycin of even the best current manufacture if large doses of the drug are given over prolonged periods.

As a rule the onset of otic symptoms, should they occur, is on the seventeenth to twentieth day if 3 Gm. of the drug is given per day.[8] On the other hand, we have seen 1 case in which otic symptoms started on the seventh day, and Brown and Hinshaw [4] reported a case in which they started on the eighty-eighth day. In 1 of our cases the symptoms started on the first day of a second course of treatments. Whether this was due to sensitization is a subject for speculation. It is hoped that it can be proved that the toxic symptoms are caused by impurities in the drug. To prove this all patients should have audiograms and quantitative caloric tests by the Fitzgerald, Cawthorne and Hallpike technic [6] before and after streptomycin therapy, and all manufacturer's names and lot numbers should be carefully recorded. The temporal bones of all patients who die after streptomycin therapy should be removed and sectioned.[9]

Fortunately the patient seems to recover from deafness in the majority of cases, and even if the caloric response remains negative the accessory balance mechanisms compensate marvelously for totally dead labyrinths, so that this need not be feared. In fact the vertigo usually lessens even if the therapy is continued in spite of it.[8]

The mechanism of the otic complications of streptomycin therapy is unclear. The cause could be either a labyrinthine or retrolabyrinthine lesion. Examination of pathologic material to date from the brains of dogs and human beings has failed to show any lesion attributable to streptomycin in the auditory tracts. Satisfactory temporal bone material is not yet available for study. It is noteworthy that most of the cases of deafness so far reported have been in patients with meningitis. In only 1 of our cases was the deafness in conjunction with tuberculous meningitis. Dr. McDermott's patients also did not have tuberculous meningitis. To be sure, deafness is not as a rule a permanent feature of this disease, but in its presence one can never be certain that supervening deafness is caused by streptomycin. This is also true of influenzal meningitis, of which we have seen 1 case with recovery,[4] total deafness and total loss of vestibular response.

Brown and Hinshaw [4] emphasize that in all their cases a low pitched tinnitus occurred and that the deafness was largely in the low frequency range. This has not been true with the cases which we have seen; in fact, 2 patients, cases 1 and 5, complained of high pitched tinnitus and they later had a greater degree of deafness for the high than for the low tones. We agree, however, that the occurrence of tinnitus may well be the sign of impending deafness. Since tinnitus is a subjective symptom, one must be careful not to induce it by suggestion.

SUMMARY

1. Eighty-one streptomycin-treated patients were examined for evidence of aural toxicity.

2. Two months after the cessation of therapy 3 of these patients showed an absence of vestibular response. During the third month after therapy 1 of these 3 has shown increasing recovery of response. All 3 complained spontaneously of dizziness during treatment. This symptom has decreased steadily and is at present not incapacitating. Except for 1 patient showing a probably unrelated high tone loss, the audiogram was normal in these 3 patients.

---

[8] McDermott, W.: Personal communication to the authors.

[9] If the bones are placed in 400 cc. of 20 per cent solution of formaldehyde for twenty-four hours and transferred to 400 cc. of fresh buffered 10 per cent solution of formaldehyde every day for four days, and are then shipped to the Department of Otolaryngology, College of Physicians and Surgeons, 630 West One Hundred and Sixty-Eighth Street, New York, with a complete history, a set of serial sections and a pathology report will be returned to the sender.

3. Another patient showed a severe loss of hearing two weeks after treatment. One month after treatment he had shown decided improvement in hearing. He had a normal vestibular response throughout.

4. Because of the possibility of complications, the indications for the use of streptomycin should be carefully considered in each case. However, when indicated the drug should not be withheld because of this danger. The occurrence of otic symptoms during streptomycin therapy should call for a reconsideration of the case before continuing the administration of the drug. If streptomycin therapy is continued, the drug with another manufacturer's lot number should be tried.

5. An audiogram and vestibular test should be performed before the initiation of streptomycin therapy.

6. The low tone and high tone losses here reported are probably not due to streptomycin, except in 2 cases (1 and 5). The low tone losses are probably due to outside interference. The losses in high-pitched tones relatively unimportant in the hearing of speech are the type commonly found in soldiers who have served in active combat.

INDUSTRIAL PHYSICAL EXAMINATIONS

Objectives and Methods

F. E. POOLE, M.D.
Glendale, Calif.

The industrial physical examination is a tool which when correctly used is an effective instrument for the proper placement of employees. Like all instruments, however, it has its limitations, and when improperly used may be ineffective or may even become a liability.

Workmen's compensation laws, holding employers responsible for the care of occupational injuries, chiefly were instrumental in the introduction of physical examinations in industry. This responsibility encouraged the attempt to weed out by examination all but the most physically fit workers, eliminating those with physical defects, who, it was thought, might have a higher accident frequency.

This method did not result in the desired lessening of industrial accidents; it was found that freedom from physical defect is not necessarily synonymous with freedom from accident proneness. Physical standards were placed so high in many instances, however, that workers physically substandard in some detail, yet perfectly capable of satisfactory employment in many occupations, were eliminated from the work force.

The use of industrial examinations as a bar to employment instead of as an aid to maximum utilization of workers naturally resulted in resistance on the part of employees to examining programs. This resistance is still found in many industries where pre-employment examinations are prohibited in the union contract. It undoubtedly results from the lack of understanding of the true objectives of industrial examinations or from suspicion of the motives of the employer in their use.

For these reasons the industrial physician not only must understand the objectives of industrial examining but must continually bear in mind his professional relationship both to the worker and to the employer. He must strive always to be impartial, to base his opinions on facts and to be uninfluenced by the wishes of either the worker or the employer.

Generally, the weeding-out concept of industrial examining has given way to a sounder policy: (1) use of the examination program for the proper placement of workers, especially those having defects which in some way limit their capacities, and (2) maintenance of the health of employees.

In the use of the examination as a placement aid, the labor union and the industrial physician share a common point of view; it is the aim of both to attain maximum utilization and protection of the worker. Labor unions whose leadership understands this principle now insist on physical examinations as a part of the advanced employee relations program.

The industrial physician should understand the importance of an advanced industrial medical program in the fulfilment of the important objective of full employment and must be prepared to render constructive service. It is my purpose to discuss the proper objectives of industrial physical examining and to examine methods by which these objectives may be most effectively attained.

The pre-employment physical examination is most generally thought of in a discussion of industrial examinations, but the complete examining program required by modern industry is far more comprehensive and may be divided into these five classes: (1) pre-employment, (2) occupational hazard, (3) maintenance of health, (4) management, and (5) special examinations.

PRE-EMPLOYMENT EXAMINATIONS

The primary purpose of the pre-employment examination is to select for the employer workers with the necessary skills and capacities to perform the work which he must have done, and to permit the worker to perform all types of work for which he is capable. To achieve this purpose, the examination must be designed to accomplish these things: (1) determination of those workers who are physically unfit for work and who must be rejected; (2) acceptance of workers who are physically capable of performing without limitation the work to be done, and (3) classification of workers with physical defects or disabilities so that they may be permitted to perform work which they are capable of doing while at the same time they are protected from the particular work which would be hazardous to them or in which they would constitute a hazard to others.

Basically, this examination requires evaluation of the worker only in relation to his work requirements and consequently need only be sufficiently detailed to permit the examining physician to formulate a reasonable opinion, based on the worker's medical history and the findings of the examination. The nature of the work determines the extent of the examination; where light, nonhazardous work only is required, a cursory examination might suffice; in industries where heavy labor or high physical capacities are required or where hazards are great, a more thorough examination is essential:

Generally, it is sufficient to determine that the worker has normal vision, hearing and use of the extremities and is free from communicable disease, serious disease of the heart or the lungs, hernia, deformity or any other condition which would be aggravated by employment.

Depending on the needs of the specific industrial plant, this basic examination may be expanded in many ways; for example, in a plant where high noise levels are encountered, closer attention must be given the ears, while in a factory where much heavy lifting is done, special attention must be paid to the body structure, back and hernias.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

I have not mentioned the consideration of psychologic factors in the examination. There is now much discussion regarding personality testing as a means of proper placement. This is a special field that requires expert evaluation of the methods in use and cannot be delegated to a few minutes of the time of the physician who makes the pre-employment examination.

When workers who are being examined exhibit definite signs of mental derangement, the physician cannot ignore these signs. If the worker does not show obvious signs of derangement, it is my opinion that the examiner should not attempt psychoanalysis, for which he generally is not thoroughly qualified. I believe that the front door to employment should be held open to all but the obviously mentally deranged, but that the physician should keep a watchful eye on the "back door"—emotional and adjustment problems which arise within the plant. When an employee demonstrates that he is maladjusted to his job or environment, the physician can assist in re-evaluation of the worker. When psychologic factors are responsible, the problem is one for the skilled clinician, who should be fully acquainted with the worker's medical history and industrial environment.

Workers accepted for employment are further evaluated by the physician, and those found to have some defect or deformity must be afforded protection.

Many systems have been developed to facilitate the use of these physically substandard workers, and refinements of these systems are being made constantly. The requirements of the successful system are: (1) simplicity, (2) ready understandability and acceptance by lay supervision and (3) minimal limitation of the worker.

The hallmark of the successful placement system, regardless of the method used, is its ease of application and maximum freedom for the employee except in the performance of work which would be hazardous to him.

These opinions have been formed over a period of years, during which time these principles have been used in the examination of more than 300,000 employees, of whom more than 15,000 physically substandard workers were successfully placed. This experience taught me, however, that the cursory examination does not give the employer the maximum benefit from the examining program.

The slight additional cost and time required for performance of the complete examination is fully warranted by its greater value. In the course of a worker's employment there are many conditions which may be of considerable importance but which can be discovered only by the use of such aids to examination as the urinalysis, the roentgenogram of the chest and the Wassermann test. Other criteria which are helpful and which may be noted in little additional time are the presence of abnormal conditions of the nose and throat, oral hygiene, weight record, pulse rate, temperature, blood pressure and deformities, including adequate description of their extent and limiting action.

In my opinion the urinalysis is an indispensable part of a desirable pre-employment examination, if for no other reason than as a means of detecting diabetes.

A general physical examination cannot be said to be complete unless a roentgenogram of the chest has been made, for minimal pulmonary lesions cannot be detected by the usual examination procedures. It is important, then, to include this laboratory aid in a complete industrial examination, especially for workers in occupations in which dusts or fumes are encountered, both because of the possibility of aggravation of an existing condition and because of the tendency of workers to believe that pulmonary conditions result from exposure to dust or fumes.

The percentage of pathologic conditions discovered in routine roentgenograms of the chest is small but sufficiently significant to warrant their routine use, especially since the small film equipment has reduced the cost to a few cents.

My experience during 1945, covering more than 15,000 routine 4 by 5 inch (10.2 by 12.7 cm.) roentgenograms of the chest, revealed 5.3 per cent significant pulmonary and 1.4 per cent significant cardiac pathologic conditions. Of the pulmonary pathologic conditions, approximately one half (2.7 per cent of all cases) were tuberculous. In two thirds of these (1.9 per cent of all cases) the tuberculosis was considered active: minimal, moderately advanced or far advanced. Stated as a percentage figure this does not seem large, but when one considers that this represents 288 cases of tuberculosis that warranted further clinical study and treatment, the problem assumes real significance.

I have had some experience with the chest roentgenologic surveys of public agencies and believe that until industry in general is better prepared to do this work such surveys are valuable for case finding; however, they should be better coordinated with the medical departments of industry, and the physician in industry should be given the findings of such surveys.

The Wassermann examination, in my opinion, is the least important laboratory test from the strictly industrial point of view. I do feel, however, that industry should cooperate as far as possible with the public health agencies in case finding, provided that these agencies are prepared to carry out a complete and effective program.

The program of physical evaluation is a part of the industrial placement program, and the examining physician, in fact, is a key member of the team for assignment of manpower. As such, his efforts should supplement and support the efforts of the other placement specialists—the interviewer, the job counsellor, the personnel adviser and the plant supervisor. He should use this opportunity to acquaint the worker with his physical status and to stimulate in him the responsibility for the maintenance of health.

Medical records obtained by examination, although confidential in nature, are no more privileged than other records of workers, and placement officials have a responsibility as great as that of the physician for proper regard for such information. The physician has no reason to object to discussion of medical information with interviewers or placement personnel when such discussion will increase the usefulness of the worker or contribute to his efficiency and safety on the job.

For physicians who inherently object to revealing medical information to lay persons, it might be well to point out that the usual physician-patient relationship is not established by the pre-employment examination, because the applicant does not choose the physician but merely submits to examination as a condition for obtaining employment. Because the usual professional relationship is lacking, medical records obtained by the examination are not privileged to the physician alone but become a part of the employer's confidential files and available to those authorized by the company to use them. Such authorization should be given to as few persons as possible, and the records should be kept in the medical department under the control of a physician, nurse or competent medical clerk.

Interpretation of physical factors or laboratory reports should be done only by a physician and should never be delegated to an interviewer or employment manager without medical training. It is impossible for a layman to translate diagnoses or laboratory reports into terms of ability to work. I have seen injustices result from such practices.

In a company employing several thousand workers in scattered locations, it was the practice to have the physical examination done close to the place of work. The completed forms, giving the detailed findings but not their interpretation, were forwarded by the physicians to the employment manager in another city, where the decision regarding employability was made. In one instance a person in a responsible position was refused employment after the company had financed the moving of his family across the United States because in the report of the physical examination there was a statement that his urine contained "sugar 2+." To the employment manager this statement meant diabetes, and diabetes meant unemployability. Both of these assumptions were incorrect.

Information transmitted to lay supervisory personnel or to personnel records should be for the one purpose of classifying the employee's ability to work, and should never reveal specific diagnoses. Classifications should be meaningful, however. Such terms as excellent, fair or poor are too general and are relatively useless. I can recommend the following classification system:

Group 1: "Unlimited." Acceptable for any type of work.

Group 2: "Limited." If a physical handicap or defect is serious enough to limit a person's working ability, constitute a hazard at work, or be seriously aggravated by some type of work, such a person will be classified as limited and placed in one or more of the following classes, which are intended to describe in lay terms the type of work which he should avoid. The reason for the limitation is a confidential matter and of no practical interest to the supervisor as long as he is aware of the type of work prohibited.

Class I—No hazardous machinery
Class II—No heavy lifting
Class III—Work at ground level only
Class IV—Avoid contact with or exposure to [agent or substance to be specified]
Class V—No extensive walking or standing
Class VI—Miscellaneous (this may be expanded to other classes as needed by the type of industry)

Group 3: "Severe Handicaps" involving special placement problems (as the blind). Transfers are not to be made without approval of the Medical Department.

Group 4: "Temporarily Unable to Work" because of a transitory condition or a correctible defect.

Group 5: "Rejection." Serious physical or mental disease or disability rendering the persons unfit for any work.

In addition to serving as a record on which the examining physician bases his recommendations for placement, the medical report is of great value to the employer as a record of the worker's physical condition at the time of employment. The worker's physical condition is subject to change with time, and in the older age groups particularly there is an increasing tendency on the part of employees to attribute progressive physical decline to occupational causes. In case of claim of alleged occupational injury, the examination record is of considerable medicolegal value, provided—and this point cannot be stressed too strongly—the record is fully and properly detailed. If it is inadequate or incomplete, it may prove a liability to the employer. The moral here is that industry can gain much from pre-employment examining, but if it is done, it must be done right; otherwise it had best be left entirely undone.

OCCUPATIONAL HAZARD EXAMINATIONS

The prevention of occupational disease is the primary objective of the occupational hazard examination. The need for this type of examination is dictated by hazards to which the worker is exposed during employment.

To determine the occupational hazard examinations required in any industry and the frequency with which workers must be examined, it is first necessary to determine the nature of the hazards involved. This is accomplished by a survey of the plant, its processes, facilities, working conditions and environment. Such a survey can be made only by an experienced industrial hygienist.

In addition to determining the conditions and processes which present occupational hazards, the hygienist is qualified to recommend safety devices and control equipment to minimize such hazards. He is best qualified to select groups of employees requiring periodic examinations, to maintain current lists of exposed workers and to establish control of new groups when processes are changed, and he, together with the plant physician, must decide the type and frequency of the examinations needed.

I wish to stress the union of the industrial hygiene surveys and the examinations as a combined control function. It is well to know that the dust counts in the sandblasting area or the lead concentrations in the air in the foundry are within normal limits, but it is equally important to know that the roentgenograms of the chest and the blood lead determinations of the workers exposed in these areas are normal. The clinical tests act as a double check on the control measures and serve to detect those with abnormal sensitivity or susceptibility.

In this type of examination it is not always necessary to do a complete physical examination, but if it can be combined with the annual health audit examination discussed later, so much the better.

Some occupational hazard examinations should be done more frequently than annually; for example, (1) audiograms to detect loss of hearing in high noise level areas should be done within thirty days after initial exposure and repeated at six month intervals; (2) complete blood counts should be done at three month intervals on employees exposed to certain aromatic solvent vapors; (3) blood lead determinations should be done at six month intervals in lead exposures; (4) roentgenograms of the chest should be done at six to twelve month intervals in dusty occupations, depending on the intensity and the duration of the exposure; (5) Geiger-Muller counts are indicated at two to six month intervals for workers exposed to radioactive material, and (6) nasal examination is required at three month intervals in chromic acid fume exposures.

It is our opinion that education of the employee is an important part of the program for occupational disease control. Employees should not be kept in ignorance of the hazards involved in their work because of the employer's fear that this knowledge might induce them to bring unjust claims for imagined injury. It has been our experience that employee morale is improved when the workers are aware of the protection afforded by the continuing plant surveys and periodic examinations.

To describe in any detail the countless occupational hazards encountered in American industry and the necessary clinical and laboratory examinations required to protect workers is not possible in this paper, but the principles involved may be illustrated.

A new bullet-proofing process for gas tanks was introduced, with the assurance of the manufacturer who supplied one of the solvents that it was nontoxic under the conditions of its use. Within a few days several workers became nauseated from the fumes, and a work stoppage was threatened because of the increasing number who became ill. Investigation by the industrial hygienist who had previously been uninformed of this new process revealed the solvent to contain benzene. Fortunately, the early complaints and immediate analysis by the hygienist prevented fatalities which could have been expected in view of the well known cumulative effect and high mortality rate of exposure to benzene.

This emphasizes the necessity for the approval of all new processes by the industrial hygienist before their use, particularly since in this case a nontoxic substitute was readily available.

Recently a new tank-sealing operation was installed, in which monochlorobenzene was used. An unpleasant odor was associated with the process. Although frequent analyses of the air proved the safety and ventilating equipment adequate to keep the fumes within safe concentrations, a great deal of apprehension was present on the part of the employees, and when, coincidentally, one employee died of a heart attack and another became ill with gallstones, the entire department was reluctant to continue work. The union demanded monthly examinations of all employees in the department. This demand was excessive, considering the nature of the hazards and the excellent controls.

Examinations at six month intervals had been planned. It was agreed to compromise by examining a portion of the exposed workers every month, thereby affording a continuous sampling check and assuring all workers that they would be checked at six month intervals.

I point out that this process was approved by the hygienist and adequately controlled at the time of installation. This fact, however, did not prevent mass fear from developing and emphasizes the necessity of educating employees regarding the adequacy of measures taken for their protection.

HEALTH MAINTENANCE EXAMINATIONS

Man power is industry's most important resource. This fact, long ignored, has been proved recently by the wartime shortages in man power, and from this experience industry has learned that as it conserves its material resources, it must now begin to conserve its man power resources.

The keystone of the program of man power conservation is the annual health maintenance audit, the purpose of which is to detect the onset of disabling disease and disability, permitting correction in the early stages and prolonging the useful life expectancy of workers.

Unlike the pre-employment examination, which is a simple process of selection aimed at effecting proper placement, the "health audit" comprises a total evaluation for the worker's physical condition, and consequently a thorough general examination is indicated. This examination must be supplemented by necessary laboratory aids, including urinalysis, blood count and hemoglobin determination and a roentgenogram of the chest.

Since the unqualified support of the worker is necessary for the success of the program of man power conservation, the professional relationship between physician and worker assumes greater importance than in the pre-employment examination. In the latter, as previously pointed out, the physician acts as a representative of the employer and exerts an influence on the worker's ability to secure employment; consequently, the only part of the traditional physician-patient relationship which exists in the pre-employment examination is the worker's privilege of knowing of any condition which the physician detects.

In the program of health maintenance the physician is *the friendly counsellor of the worker, seeking to assist* him in prolonging his useful life expectancy, and a limited physician-patient relationship is created. This differs from the relationship of the private physician with his patient in that the examining physician, having found a condition requiring treatment, refers the worker to his private physician for further diagnosis and treatment. He does not generally undertake the treatment of employees.

The necessary cooperation of the worker is obtained for the program when he fully understands his relationship with the physician, the purpose of the examination and the fact that his employment status will not be affected by the conditions revealed by the examination—unless such change will be to his benefit. This point is fundamental, and its principle must be zealously guarded by the physician. Any suspicion on the part of workers that the examination may be used by the employer to eliminate from the working force those who show signs of physical deterioration will result in immediate reaction against the entire program and will doom it to failure. The physician is the key factor in preventing corruption of this principle. He must treat all information he receives through the examination in professional confidence and must never disclose privileged information to the employer or supervisory personnel without the consent of the worker.

When the program for the conservation of man power is properly conceived and executed, it produces significant benefits for both employer and workers. The Metropolitan Life Insurance Company, for example, has given annual health audits to its employees for many years and has determined scientifically that the average useful life expectancy of workers is prolonged by more than 24 per cent through this program for the protection of health. The benefits of this longer earning life are readily understandable as they affect the worker, but have only recently been appreciated by industry. In this age of specialization, however, when the period required to acquire necessary occupational skills is being steadily lengthened, the savings to the employer in replacement cost of skilled workers under a program for the protection of health become obvious.

I might cite many examples of the early detection of disease such as tuberculosis and diabetes in workers who had no complaints, as well as cases in which it was necessary to prove to workers with functional complaints that no organic pathologic conditions existed. This phase is as important as the detection of real disease, for functional conditions brought on by the nervous tensions of work and maladjustment can be as disabling as organic disease.

This is well illustrated by the case of a supervisor of inspection who at the time of his examination complained of indigestion, pain about the heart, excessive fatigue, poor sleep and loss of weight. He was certain that he had some serious condition, such as cancer of the stomach. It was learned that he was intense in his work, put in long hours and worried greatly over the possibility of errors in his job and the resulting consequences to the airplane. He had similar but less severe symptoms the year before, but they had cleared up during the course of recuperation from a minor operation.

Physical examination revealed no evidence of organic disease, and my colleagues and I were able to convince him of this through the use of laboratory tests. He was, however, suffering from a severe state of chronic fatigue, and there was no doubt that his condition was in part related to his inability to remain the master of his job. A leave of absence was arranged, and a program was outlined for him to follow. On his return to work a new assignment was arranged, which carried less responsibility. He has been satisfactorily adjusted and productive in his new job for over a year.

MANAGEMENT EXAMINATIONS

The one resource without which industry cannot operate successfully is management and supervisory personnel, and it is the purpose of the program of examination for executives to conserve this all-important personnel. Executives are most capable of understanding the purposes of the program having to do with health and are best situated to appreciate the findings of the examination and to obtain necessary treatment.

The business of management has its peculiar occupational hazards, and these are related mainly to the mental and nervous processes rather than to the physical. The task of guiding industry in these complicated modern times subjects the executive to continuous nervous and emotional stimuli, which, acting through the autonomic nervous system, frequently effect functional alterations with accompanying disturbing symptoms. These are usually associated with the gastrointestinal or cardiorespiratory system.

It is the role of the physician to determine whether these symptoms result from organic pathologic conditions or functional disorder. This requires a thorough, complete examination, including urinalysis, blood count, serologic test, electrocardiogram and roentgenograms of the chest and the teeth.

The person who experiences symptoms of a functional nature must actually be convinced by being confronted with positive evidence of the absence of organic disease. It may be necessary, therefore, to prove that a disorder which he believes to be pathologic results from a functional cause. Such proof to support the clinical observations is obtainable through the use of many laboratory aids. The promiscuous use of laboratory tests is not advocated.

In this examination the highest form of physician-patient relationship must be developed. The industrial physician becomes the confidant of the executive and must be available to him for consultation and reassurance. Since the physician is familiar with the executive's daily industrial problems, he is better able to counsel him.

The invaluable assistance which a physician may render not only to the executive but also to the company is illustrated by the case of an experienced executive in whom, in the midst of an extended period of negotiations under adverse conditions, distressing cardiac and gastrointestinal symptoms developed. His annual examination, which had been done a few months previously, was immediately supplemented by gastrointestinal roentgenograms and another electrocardiogram. A diagnosis of duodenal ulcer and frequent extrasystoles was established. He was placed on an appropriate treatment regimen and his activities were reorganized. Immediate improvement was noted, and he was able to continue the assignment to its completion. He has continued his treatment regimen, and recent rechecks of the laboratory tests indicate complete recovery.

This is an example of the combination of functional and early pathologic conditions. The ulcer was readily treated by diet, the cardiac arrhythmia soon subsided under the reassurance and the lessening of the load of work, and the executive was enabled to carry on without loss of time.

SPECIAL EXAMINATIONS

An inestimable number of special examinations are required by industry in general to cope with specialized problems not falling within the scope of the four classifications previously discussed. I shall confine my discussion of these to (1) examinations required by those workers whose employment is contingent on their maintaining a high level of physical fitness and (2) examinations which are used for continuing placement of the worker after employment and which feature in the program of employee relations.

Among the occupational groups where top physical condition is a prerequisite for employment are airplane test pilots, marine divers, locomotive engineers, bus and truck drivers, especially long distance drivers, professional athletes and others. Our experience has been with test pilots, and as their problems are generally indicative of the nature of special physical requirements for other groups also, a discussion of special examinations required for pilots may be illustrative.

The test pilot has a tremendous responsibility to carry under trying conditions. He is charged with testing new designs for airplanes or newly manufactured models. To complete his assignment he must exceed all the performances required of the particular airplane in its regular use; consequently, his physical strain is greater than that experienced by any other pilot. Further, since this strain results from high speeds, high altitudes, extreme concentration and nervous tension, psychomotor and psychologic conditions are important factors.

In addition to peak physical fitness, the pilot must have perfect vision, nervous balance and physical endurance, and his examination must be specially designed to test these factors to the limit.

The importance of thorough examination is pointed out by the case of a pilot with exceptional ability and experience who casually complained of a symptom of pain in an extremity. Thorough investigation, including neurologic examination, pointed to the probability of a serious nervous system lesion. Although he was scheduled for an important flight operation, the pilot was grounded, and further clinical investigation was undertaken. The decision to ground him was fortunate, for during the period he would have been flying his condition reached a climax which would have produced disastrous consequences. Without a thorough examination it is probable that a minor complaint of this nature might have been overlooked.

Physical fitness must be coupled with satisfactory mental adjustment for safe operation in flying. Mental maladjustment is just as damaging to a pilot's efficiency as physical deterioration, and the case of a senior pilot illustrates this point. He requested a leave of absence based on a complaint of excessive fatigue following each trip and the inability to become rested before the next trip. He had frequent headaches, felt irritable at times and was inclined to worry unduly over minor details. He attributed his symptoms to the fact that he had not had a vacation for over a year and so reasoned that he should have three months off in order to rest. He started flying when he was 16 years old, had a commercial job at 20 and had flown all sorts of airplanes under the most difficult conditions. He looked back on these experiences as having been associated with a great deal of luck; now, with modern equipment he found himself worrying over minor mechanical problems. He had never had an accident in his fourteen thousand hours but admitted that if any one asked him about the safety of air travel, he could not be convincing because he knew too many things that could go wrong.

His physical examinations had never revealed any abnormality, and the result of the reexamination was the same. The interview developed the fact that he had started flying so early in life that he had not completed more than a high school education and that he consequently felt inferior to the many college graduates with whom he was competing. He had come to the feeling that experience no longer compensated for his lack of additional formal education. He was not desirous of advancement to larger equipment.

This problem centered around a feeling of inadequacy in competition with more formally educated men and the development of a state of anxiety which had become so deeply fixed that it was doubtful whether he could satisfactorily be readjusted to his job. Following his leave of absence he returned to work for a temporary period but soon had a recurrence of his previous symptoms and had to make a readjustment into a new occupation.

This emphasizes the necessity of extending the examination beyond the purely physical to include personality evaluation in order to arrive at a satisfactory solution of the individual problem.

The industrial physician's responsibility for the correct placement of employees is not terminated at the time of hire, but continues throughout the worker's employment. When evidence is found that the worker has become maladjusted in his occupation, it is the physician's responsibility to reevaluate his physical capacities and mental adjustments to determine what occupational changes, if any, are necessary to establish readjustment. Instances of maladjustment are usually brought to light by plant supervision, and the physician serves as an adviser to the supervisor in this type of examination. His recommendations should assist the supervisor in effecting a better placement for the employee when this is found necessary. Since the worker's physical condition is constantly changing and may be deteriorating steadily, replacement is unavoidable in many cases and should be guided by the physician.

Employees maladjusted to their work for physical, nervous or mental reasons fall into two groups: (1) those who seek to minimize their limitations and seek greater occupational opportunities than they are capable of performing, and (2) those who seek to obtain special privileges, lighter work and perferred shifts by taking maximum advantage of their difficulties, real or imagined.

With the first group the industrial physician must point out to the worker the nature of his limitation and its effect on his physical capacity. He must also inform him of the requirements of the job he desires and the possible results if he were to perform the work from which he has been prohibited.

With the privilege-seeking group the physician's task is more difficult. Having determined their real physical capacity, he is faced with the necessity of convincing them that they are physically capable of performing the work requested of them—and of securing their agreement to do so. Since the malingerer, the loafer and the socially insecure fall into this group, the physician's task is a difficult one, and it is unfortunate that the percentage of successful replacements is low.

Minor physical complaints are frequently used as subterfuges to obtain a change of jobs desired by the worker for other reasons. An example is the case of a young male employee who requested a change from the evening to the day shift on the basis of the aggravation by the night air of an existing bronchitis and sinus infection. The working conditions on this shift were not such as ordinarily to aggravate such a condition; therefore his request was denied. He used every pressure to try to force the change on the basis of his health. It was discovered that his real reason for desiring the change was to allow him to continue playing night baseball, which gave him a much greater exposure to night air than did work within the plant.

When it is impossible to satisfy workers in either of the two groups mentioned, a union grievance may result and the problem becomes one of employee relations. In the solution of this problem, the company must depend in large part on the wisdom of the physician. If he has used good judgment and has carefully documented his observations, they carry great weight in the employer's defense against the worker's grievance.

Employees returning to work after absence due to illness or injury should be reevaluated before being allowed to return to work, as it is obvious that sickness or injury may alter an employee's physical capacity for work either temporarily or permanently. The industrial physician must be sure in setting up a procedure to screen employees returning to work after illness or injury that the procedure is practical, both from the medical and from the supervisor's point of view.

From the medical point of view, these examinations should not be stereotyped but should be suited to every individual case. It affords the opportunity to reexamine employees who have not been examined for a year or more and to reevaluate by careful physical appraisal the working ability of those who have had a serious injury, illness or operation. Opinions expressed by the employee's private physician should be carefully considered by the industrial physician, but the latter is usually better able to decide whether or not the employee can return to his regular job, because of his knowledge of the working conditions within the plant.

The industrial physician is not interested in seeing personally all employees who have been absent with minor illnesses for three or four days. If the procedure requires every one who has been absent because of illness or injury for three days or more to clear through the Medical Department before returning to work, the majority of the screening must then be delegated to nurses. I have had experience with extremely rigid medical controls to the point of having every absence of one day or more checked through the medical department. In theory, such a system had many technical advantages. However, the inevitable delays in getting employees to their places of work and arbitrary assignment of a function to the medical department which was largely a function of supervision led to poor cooperation between the medical department and the supervisory personnel.

The policy was changed to place the primary responsibility for releasing an employee to work on his immediate supervisor. In the use of this discretionary power the supervisor was given every aid of the medical department. The relationship between the medical department and the supervisory personnel was greatly improved by this change of emphasis from one of a checking function to one of a service function.

Management in small plants is not generally aware of the need for good medical service, and it is therefore the responsibility of the profession not only to provide good industrial medicine but to undertake an educational program [illegible] efits resulting therefrom. Further, [illegible] must assist management in obtaining medical service at a cost compatible with the profits of small industry. This requires the grouping of small plants into units which may be economically serviced by the profession. The industrial physicians must ceaselessly strive to extend the benefits of the profession to all industry.

ABSTRACT OF DISCUSSION

Dr. R. R. Beard, San Francisco: This paper presents a valuable formulation of facts and opinions which I know to be based on sound experience concerning industrial medical examinations. If I understand Dr. Poole correctly, I disagree with the concept expressed in his statement that the usual physician-patient relationship cannot exist at preplacement examination. That is only partially true. If the preplacement examination is done in an atmosphere of friendly interest, especially with time being taken firmly to establish in the worker's mind the idea that medical examination of his fitness for the contemplated job is for his own advantage, then two purposes at least will be served: first, one will get more complete and more accurate information on which to base one's decision as to placement; second, it will establish an effective relationship for the starting of the health maintenance or constructive health program. It is possible to keep preplacement medical examination records confidential, and I think it is essential. Except where an industrial accident compensation claim is involved, it is our practice to withhold the diagnoses from management. We encourage our employees to talk over their whole medical situation with their supervisors, but if they don't want to do so we keep the diagnosis to ourselves, and what we give to management is a clear statement of the limitations of activity imposed on the individual by the abnormalities which we find, and also the outstanding strengths of the individual. The responsibility for informing employees of abnormalities discovered should not be limited to major defects. The most effective health education is conducted on an individual basis, and the occasion of a medical examination offers an excellent opportunity to give good instruction. There is a challenge to the physician in each preplacement examination, for he is serving not only to find things that will limit the activities of the new employee but also to find ways in which that individual can be bettered. The common acceptance of a twelve months interval for reexamination seems to me to have little objective basis. We may benefit by employing knowledge gained from the school health people in this respect. It has been found there that it is more useful if the interval between examinations is lengthened and a more thorough examination is done at each. If one can concentrate on the individuals who show special need for surveillance at the original examinations or because of excessive absenteeism or advance in age, this can help to maintain the interest of the examiner in doing the work. If he is doing something more than just a routine examination but is looking for something special, he will get more satisfaction from it.

ETHER AND HUMBUG

EVARTS A. GRAHAM, M.D.
St. Louis

It is a great honor to be asked to participate in this centennial celebration of the first public use of ether anesthesia under the auspices of this great medical school and the internationally famous Massachusetts General Hospital, an institution which, in addition to its pioneer use of ether, has to its credit the revelation of the true nature of appendicitis and acute pancreatitis by the great Fitz, as well as many other important discoveries. I accepted the invitation of Dr. Means and Dr. Churchill with great humility and with doubt that I am qualified to do proper justice to the occasion.

The simple remark of Dr. Warren at the finish of the successful demonstration, "Gentlemen, this is no humbug," has always interested me. Its simplicity and brevity suggest a deep and awe-inspiring effect on his emotions, as if he could think of no adequate words with which to express his feeling. Doubtless he could not, and his intense emotional reaction would indicate that he fully realized that the key had been found which would open the door to future developments which could only be faintly seen from his vantage point. Perhaps also he had a sufficiently prophetic vision to see that in time there would be an annual celebration of the event at which a speaker would be invited who would stimulate or even bore his audience by an address which would be much too long and might even contain some humbug. But why did he think it necessary to state that the demonstration was no humbug? If he had been speaking one hundred years later he might have said "Gentlemen, this is no baloney." For the word "humbug" at the time was considered so slangy that, according to Mencken,[1] when William Cullen Bryant became editor of the New York *Evening Post* he refused to permit its use in that newspaper.

We of a later age whose privilege it has been to see medicine established on a firm scientific basis can scarcely appreciate its state at the time at which Morton and Warren conducted their successful demonstration of the use of ether anesthesia. One wonders how much humbug the old Egyptian mummy present in the oper-

ating room on the occasion must have heard in his corner. If it could have had any critical judgment and the power of speech it might have raised its voice to say that in its own last illness, thousands of years ago, it had been the victim of medical humbug and that it had heard plenty of humbug addressed to the students of Harvard Medical School in the same room which was about equally unscientific to the medical humbug of a thousand or more years ago.

In 1846 homeopathy was rampant, and so-called regular medicine had just emerged from the domination of the systematists. Those who have recently received their M.D. degrees perhaps do not even know what is meant by the term "systematists." Well, these were zealots who attempted to place all medical symptoms and diseases into simplified systems. The most ardent systematist of his day in the United States was Benjamin Rush of Philadelphia, who was also generally admitted by his contemporaries to be the most outstanding American physician of his time. In 1796 in a lecture given to students at the University of Pennsylvania and subsequently printed and published in his "Lectures on the Practice of Physic" he made the statement, according to Shryock,[2] "I have formerly said that there was but one fever in the world. Be not startled, Gentlemen, follow me and I will say there is but one disease in the world. The proximate cause of disease is irregular convulsive or wrong action in the system affected. This, Gentlemen, is a concise view of my theory of diseases."

Could anybody today imagine any more humbug than that? Yet that statement came from the lips of the most prominent physician in the United States at the time, one who Lettsom of England and Zimmermann of Germany said after his death should be immortalized. Speaking now to a New England audience I may say that it is to the credit of Elisha Bartlett, a New Englander, that he detected the humbug in Rush's writings and, again according to Shryock,[3] in 1843, three years before the event which we are celebrating, had this to say about the opinions of Rush, the great systematist: "It may be safely said that in the whole vast compass of medical literature there cannot be found an equal number of pages containing a greater amount and variety of utter nonsense and unqualified absurdity." Too bad Elisha Bartlett is not alive today to express his views of the writings of another New Englander, Mary Baker G. Eddy!

Of course in 1846 there was no surgery in the modern sense. In fact there were no surgeons as we understand them today. No specialization in medical practice had occurred, and every doctor was a general practitioner. Even as late as 1880 when the American Surgical Association was founded by Gross the original members were all general practitioners. In 1846 the operations that were performed were mostly on the extremities in addition to the removal of bladder stones. The abdominal and other body cavities had been rarely invaded. Speed was considered to be one of the most important factors in the success of an operation, chiefly because of the absence of satisfactory anesthesia. The best surgeons performed a thigh amputation in about three minutes, and Cheselden of London is reputed to have completed an operation for removal of a bladder stone in fifty-four seconds. It is true that in a few cases the operation of ovariotomy for ovarian cyst, initiated by McDowell of Danville, Ky., in 1809, had been performed successfully, but operations within the abdominal and other body cavities were extremely rare and still more rarely successful.

DRAWBACKS TO PROGRESS OF SURGERY

What was needed to advance surgery to make it safe and practical were first of all a more scientific attitude toward medicine as a whole, with the elimination of the humbug, and more specifically these three developments: a satisfactory method of removing pain (surgical anesthesia), the control of infection and the satisfactory prevention and treatment of surgical shock.

When one contemplates the horror attendant on an operation before Morton's time one is compelled to wonder how any one with even ordinary sensibilities could have undertaken to practice the art of surgery. The agonizing pain, the inevitable infection of the wound and the strong probability of the death of the patient were features which would not be likely to attract sensitive men to this profession. Yet we know that many who did practice surgery were sympathetic. In the case records and notes of operations performed about the year 1800 in the New York Hospital, edited by Pool and McGowan[4] a few years ago, there are frequent comments on "the fortitude evinced while under the knife." Rarely if ever nowadays would one find a note in a patient's chart commenting on how well he withstood pain. Are we perhaps less sympathetic because we are supplied with a large armamentarium of pain-killing drugs? Dr. John Brown's "Rab and His Friends," published in 1859, with which doubtless many of you are familiar, portrays an exceedingly sympathetic understanding of the horror and anguish associated with an operation. Again, the kindly sensitive face of Lord Lister bespeaks only the greatest sympathy.

The abolition of pain during an operation through the discovery of the use of ether at once removed one of the three obstacles to the development of surgery. To the layman this important discovery usually implies only that now the patient could undergo an operation without the pain which formerly had to be endured. Actually, however, as with most fundamental discoveries, the results were much more far reaching. Speed no longer was the important factor. Slapdash surgery was supplanted by slower but more careful work. Again, the muscles of the patient were relaxed and there was no struggling. Many modern operations could not be performed without the relaxation of the patient, and in all operations it is desirable that there should be no struggling. But aside from the beneficial effect on the human patient the discovery of anesthesia made it possible to operate on animals without pain. As a result, therefore, of experimental operations painlessly performed on animals a tremendous amount of knowledge was acquired which not only advanced the art of surgery but affected the whole realm of medicine. The functions of organs could now be studied by noting the effects of their removal. For example, how could one suppose that the pancreas was concerned in the use of sugar except by the fact that its removal immediately resulted in the condition of diabetes? Various operations on the stomach and intestines of animals taught the physiologists much about the processes of digestion in addition to paving the way for the surgeons to apply some of those operations to man for curative purposes. Indeed, practically all of our fundamental knowledge of the functions of our various organs has been derived from experimental operations on animals, and most of that knowledge has been acquired since it has been possible to use general anesthesia for the experiments. The development of the scientific basis of medicine, therefore, has depended to a considerable degree on the existence of a method of anesthetizing experimental animals. Dr. Warren might have gone further and said "Gentlemen, this is a severe blow to humbug."

[4] Pool, E. H., and McGowan, F. J.: Surgery at the New York Hospital One Hundred Years Ago, New York, Paul B. Hoeber, Inc., 1930

The prevention of infection during operations, which was the second of the requirements for the advancement of surgery, was largely the work of the Englishman Lister. The dramatic story of his work is familiar to every medical student and needs not be repeated here. One aspect of it, however, deserves emphasis, particularly to young men who are about to embark on surgical careers. What I have in mind is the fact that the young surgeon in Glasgow, Lister, became acquainted with the work of the young chemist in Paris, Pasteur, from which he received much of the inspiration responsible for his epoch making contributions to surgery. One often gains inspiration and ideas from a knowledge of work in a field apparently remote from one's own.

Even after methods had been established for the prevention of pain and infections during operations, patients too often died for reasons which were by no means clear. The blood pressure would fall, the pulse become rapid and weak and the patient's skin cold and moist. The condition finally became designated as "surgical" or "traumatic shock." Although there are still some poorly understood features of shock, methods of preventing and treating it are now so well known that the condition no longer haunts the surgeon as it did a couple of decades ago. The contrast between the incidence of shock in the last war as compared with the first world war is dramatic. Risking the accusation of being chauvinistic, I like to think that the conquest of surgical shock, like the contribution of surgical anesthesia, has been largely American. One of the first to undertake a serious experimental study into its nature was George Crile, who in 1899 showed the importance of raising the blood pressure by the transfusion of fluid. Although many of his later ideas on the nature of shock were not accepted, he made surgeons everywhere "shock conscious" by his frequent writings and emphasis on the condition. Although blood transfusion, which Crile and others before him recognized as being the ideal remedy for shock produced by hemorrhage, was not practical and safe until the Austrian Landsteiner, also in 1899, demonstrated the different blood groups, the practical and convenient method of administering the blood by the addition of sodium citrate to prevent its clotting was the idea of Lewisohn of New York shortly after World War I. It is doubtful that the transfusion of blood could have been practiced very generally without the simple but important modification of technic that Lewisohn proposed. The modern blood bank, which has made blood readily available for the prevention and treatment of shock in the operating room, is chiefly an American contribution. Moreover, mention should be made of the dried plasma devised by Stuart Mudd and first used in shock by Ravdin, both of Philadelphia, and of the work of your own Cohn in the preparation of albumin and of fibrin foam, the first of several agents developed from the blood to assist in the prevention of hemorrhage, a precursor of shock. It is a pity that time will not allow of a discussion of the important work of Blalock and many others.

Thus two of what seem to me to be the three major foundations of modern surgery have been largely American contributions. We surgeons can take justifiable pride in this fact.

INTERN, PHYSICIAN AND NURSE ANESTHETISTS

But, to return to the subject of anesthesia, Morton could hardly have foreseen that a century after his momentous demonstration of the use of ether there would be many substances available for the elimination of pain during an operation and that many different technics would be available and necessary for the different uses of the anesthetic agents requiring knowledge by those who would use them for their complicated actions on the living body. Likewise it probably did not occur to him that a separate division of medicine known as anesthesiology would arise whose practitioners would be known as anesthesiologists. It's lucky for them as well as for the rest of us that Oliver Wendell Holmes coined that word "anesthesia." It would be horrible to contemplate what we might have suffered if Bigelow's[5] word "insensibility" had remained. What would the present day anesthesiologist then be called?

For more than half a century after the demonstration of ether anesthesia its practice was regarded as so simple and free from danger that it was considered that no special knowledge or training was necessary in order to "give an anesthetic," to use the popular expression current among the house staff. The youngest and most inexperienced interns were entrusted with this complicated and dangerous performance. In retrospect it seems incredible that this could have been so. Yet I well remember my own terrifying experiences as a young intern anesthetist. That many patients died as a result of improperly administered anesthesia goes without saying.

For some strange reason the profession of physician anesthetist, or anesthesiologist, did not make a strong appeal in this country until very recently. Those with M.D. degrees were not attracted to a career as professional anesthetist, although in England, since the early days, probably most of the anesthesia has been entrusted to physicians. In order to obtain better anesthesia than that provided by the unskilled interns, about 1907 Dr. George Crile and the Mayo brothers trained specially selected graduate nurses to take charge of the anesthesia in their clinics. Shortly after the first world war a school for the training of nurse anesthetists was established at the Lakeside Hospital, Cleveland. Later similar schools were created elsewhere, and hundreds of nurses were trained in the art of administering anesthetic drugs. No one can deny that the creation of the nurse anesthetist resulted in a vast improvement in the quality of the anesthesia and of the surgery throughout the country. The slipshod practice of having it conducted by interns and still worse by the referring physicians gave way to the employment of professional anesthetists, albeit nurses. Now, however, more and more doctors of medicine are taking up careers as specialists in anesthesiology. This long delayed movement is in the right direction. A splendid example is afforded in your own Dr. Henry Beecher, who is training young doctors to become experts in this field, just as young surgeons and other specialists are being trained, by devoting a period of years to the process. The physician because of his superior education in the science of medicine is better qualified than the nurse to understand the many complicated effects of the anesthetic drugs on the body, and he is more likely to advance our fundamental knowledge of the field.

---

[5] Bigelow, H. J.: Insensibility During Surgical Operations Produced by Inhalation, Boston M. & S. J. 35: 309, 1846.

There are some prominent anesthesiologists who would eliminate completely the nurse anesthetist. They have even supported legislation in some states which would make it illegal for a surgeon to engage the services of a nurse anesthetist. This, it seems to me, is a most unrealistic attitude to take. There are seven thousand hospitals in this country but at most only a few hundred professional physician anesthetists. They can conduct only a small fraction of the anesthesias in the country. Who will handle the rest? Shall we return to the old custom of having the inexperienced intern or the doctor who refers the patient to the surgeon administer the anesthesia? God forbid! The best solution to the problem then is to encourage the training of the nurse anesthetist until there are enough physician anesthesiologists to fill the demand. There has been no opposition, as far as I know, to the idea of the laboratory or x-ray technician. Why should there be opposition to the nurse anesthetist technician? In the larger hospitals she should be under the direction of an anesthesiologist who holds the M.D. degree and has spent several years in graduate training in his field. But in the smaller hospitals, or in those in which a physician anesthesiologist is not available, she will prove invaluable. There is no doubt that already she has saved the lives of thousands who would have died if they had been subjected to the kind of anesthesia which the unskilled physician gives. The possession of the M.D. degree by itself certainly does not qualify one in a professional sense to administer an anesthetic drug safely.

If we are to continue to have nurse anesthetists for at least an indefinite period, where are they to be trained? Should they not receive their instruction in this dangerous art in our best teaching hospitals, where they can have the benefit of the teaching of the best professional anesthesiologists, or should they be compelled to seek their instruction casually in doctors' offices? I think there can be only one answer to this question. Yet again there are those of great influence in this new profession of anesthesiology who would, if they could, abolish all opportunities in our hospitals for the nurse, or for that matter any one not possessing the M.D. degree, to obtain instruction in the art of anesthesia. What would Morton, the dentist, think of that, the man whose epoch-making work we are celebrating today? Let us not have any humbug in affording the benefit of that work to all the people.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(Continued from page 26)

(NOTE.—*Following is the tenth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 10. *The Question of Cultism in Medical Practice*

1870-1874

1870

WASHINGTON, D. C.

As the delegates assembled in Washington for the Twenty-First Annual Session in 1870, there were signs of disaffection within the Association. Majority and minority reports from the Committee on Arrangements were promptly referred to the Committee on Ethics for decision. Several members took a hand in the argument. Eventually it developed that the Massachusetts Medical Society was tolerating in its midst men acknowledged to have become homeopaths and eclectics. The committee felt that the society could not be barred from the current convention because of the presence of these members but felt that unless the said society took the necessary steps to purge itself of irregular practitioners it ought not to be entitled to future representation in the American Medical Association.

There was also some disturbance over the number of delegates from the District of Columbia.

THE FOUNDING OF THE JOURNAL

Most important, however, was a resolution introduced by Dr. S. D. Gross to the effect that the Transactions should be published in a journal to be called The American Medical Association Journal, issued monthly under the supervision of a competent doctor. The resolution was referred to a committee of five for their consideration.

At this convention also a resolution was introduced urging the government of the United States to establish a national school of medicine. This resolution was referred to a committee for report the following year.

Much of the time was taken in the consideration of the right of specialists to issue cards announcing their specialties and the right of a physician not a resident of any given state to represent that state in the House of Delegates.

ACC. NO. 57

A committee was established to prepare a nomenclature of diseases. By this time also there was some concern over the technic of teaching residents and interns in hospitals, and the society resolved that it was not within the purview of the general management of a hospital to interfere at all with the subject of medical instruction, which belongs to the medical staff.

Far in advance of its time was a resolution requesting the editors of medical journals to refuse to notice in their journals all "patent" medicines, instruments, works of unprofessional or unscientific character, nonchartered institutions or hospitals and the cards of specialists.

ADMISSION OF NEGRO DELEGATES

A considerable division of membership of the Association arose as well over representation of the National Medical Society in the District of Columbia, the Howard Medical College, Freedman's Hospital and the Smallpox Hospital. The majority report made by N. S. Davis would have barred these institutions because of charges that had been filed against them. The minority report, headed by Dr. Alfred Stillé, recommended their admission. The majority report was sustained by a vote of 115 to 90, and these institutions were barred from membership. The nature of the charges was not at first made clear. On the next day, however, the question was again raised and a motion from Dr. G. S. Palmer of Maine demanded the reason for the barring of men from Howard University. Dr. Davis promised to give in writing the reason for the action of the majority of the committee. When Dr. Davis presented his report, it was worded to indicate that the delegates from the medical department of Howard University were barred because they were also members of the National Medical Society of the District of Columbia and that it had been brought to the attention of the Committee on Ethics that the said National Medical Society recognized and received as members medical men who were not licensed to practice. Following the presentation of this report there was further debate, after which Dr. H. R. Storer of Massachusetts offered the following statement:

> Resolved, That inasmuch as it has been distinctly stated and proved that the consideration of race and color has had nothing whatsoever to do with the decision of the question of the reception of the Washington delegates, and inasmuch as charges have been distinctly made in open session today attaching the stigma of dishonor to parties implicated, which charges have not been denied by them, though present, therefore
>
> The report of the majority of the Committee on Ethics be declared, as to all intents and purposes, unanimously adopted by the Association.

This motion passed 112 to 34.

THE LIBRARY

New at this time was the report of the librarian of the American Medical Association, who had been engaged since the last annual meeting in endeavoring to carry out the expressed wishes of the American Medical Association with regard to the formation of an American National Medical Library to be located at Washington, D. C. A circular had been sent widespread and a good many books had been received, but the Congressional Library Committee had not authorized the Library of Congress to receive the books belonging to the American Medical Association as a special deposit. Therefore a room had been fitted up in the Smithsonian Institution to house this library, and a device had been engraved for use on labels of the books belonging to this collection.

ANTICIPATING THE NEED FOR QUININE

Significant at this time was the publication of a memorial that had been sent to the Congress trying to get the Congress to plan for cultivation of the cinchona tree in the United States. When the Japanese occupied Java as one of their first steps in World War II, we realized the need for an American source of cinchona. Had it not been for the development of the synthetic quinacrine hydrochloride (atabrine) and the utilization of some cinchona from South America, we might have found ourselves in a serious state in the war against malaria.

1871

SAN FRANCISCO

Now the Association journeyed for the first time to the Pacific coast and held its meeting in May in San Francisco.

The committee to establish a journal had no report. The committee on nomenclature of diseases reported progress. The committee on medical literature had no report. The trip to the Pacific coast may have exhausted the delegates.

Now also there was introduced for the first time the concept of an organization within medicine itself to raise the standard of medical practice. A resolution proposed that the American Medical Association take measures to establish a National Academy of Medicine to which men of distinction could be elevated from the ranks and that a board of examiners function to govern entrance to this academy. This was no doubt the first step toward certifying boards for specialists.

The Massachusetts Medical Society reported that it had expelled from fellowship all those who publicly professed to practice in accordance with any exclusive dogma, whether calling themselves homeopaths, hydropaths, eclectics or what not.

From the California State Medical Society came a resolution congratulating the states of Massachusetts and California on having established departments of state medicine and urging that all the states set up departments for the prevention of disease and the correction of those agencies which injure the human race and, furthermore, that as soon as six states should set up such departments a National Health Council be formed as an auxiliary to the American Medical Association.

By this time 339 volumes including pamphlets and monographs had been collected in the Smithsonian Institution, but scarcely an American textbook had been added.

WOMEN IN MEDICINE

In his presidential address Dr. Alfred Stillé embarked on an attack on women in the medical profession, admitting their right to study medicine and to practice it but, in general, arguing that they could never qualify to eminence in the profession. Here is an example of his logic:

> Certain women seek to rival men in manly sports and occupations, and the "strong-minded" ape them assiduously in all things, even in dress. In doing so, they may command a sort of admiration such as all monstrous productions inspire, especially when they tend towards a higher type than their own.

[illegible] Library
D. M. C. Medical College

> But a man with feminine traits of character, or with the frame and carriage of a female, is despised both by the sex he ostensibly belongs to, and that of which he is at once a caricature and a libel. In every department of active life man excels woman, excels her even in things for which she is esteemed most fit. In the arts of design, in painting and sculpture, no woman, albeit the artist's career has always been open to her, has ever risen far above mediocrity; while men have excelled women in not a few employments which are regarded as essentially feminine. In the art of cookery, for example, no woman ever occupied the first rank; and in more than one capital, male hairdressers and dressmakers set the fashions in which court ladies and city dames contend for the palm of beauty.

And he concluded this talk with even more bad logic:

> On the whole, then, we believe that all experience teaches that woman is characterized by a combination of distinctive qualities, of which the most striking are uncertainty of rational judgment, capriciousness of sentiment, fickleness of purpose, and indecision of action, which totally unfit her for professional pursuits. Judged by one of her own sex, the verdict is in these words: "The ignorance, the inexactness, the untrustworthiness, the unbusiness-like ways of women, are appalling. Men are as bad as they can be, one is sometimes tempted to say; but apparently they cannot be so bad as women in these respects. Long ages of experience have, at least, educated them into a consciousness of the difference between yes and no; but women have yet to learn that they are not one and the same word. . . . They seem to lack a moral sense, or a mental perception, or whatever the faculty is which makes one capable of contracting an engagement. They do not comprehend its nature. It has for them no more binding force than a rope of sand. They break it with a serene unconsciousness that anything is broken, or that there was anything to break.
>
> If, then, woman is unfitted by nature to become a physician, we should, when we oppose her pretensions, be acquitted of any malicious or even unkindly spirit. We may admit that she is in some sense a perfected man, and was created even a little less lower than the angels; we may admit that, guided by her affections, her judgments sometimes resemble inspirations; but in the business of life, and especially in the practice of a scientific art, it nevertheless may be true, and probably is so, that she usually displays a strange ignorance of the logic of reason, and a profound contempt for the logic of facts.

And he closed his address with a vigorous defense of the use of alcohol in medicine and an attack on those who were fighting the battle of temperance.

1872

PHILADELPHIA

The meeting of 1872 opened in Horticultural Hall but moved shortly to Presbyterian Church because people could not be heard in the original place of meeting. The sessions were largely routine on the first day, with some undistinguished papers and some routine considerations in the House of Delegates.

Then on the second day Dr. S. B. Merkel proposed to bring before the Association George Thomas, "a native of Brazil, who, although externally well formed, can move his heart about at will; and can also whirl the abdomen like a huge ball, with an undulating motion, around the umbilicus." This offer was referred to the Section on the Practice of Medicine and Obstetrics.

There was an extensive report from the committee on nomenclature of diseases, with a recommendation that it be referred for publication, but a minority report said that the matter was too important to be adopted in a hurry and suggested, rather, that extra copies be printed for circulation to the members of the medical profession so that their opinions might be ascertained.

The motion to establish a National Academy of Medicine was brought out and recommended for passage, but the motion was lost and the subject dropped.

STATE HEALTH DEPARTMENTS

The Committee on a National Health Council indicated that it had circularized thirty states with a view to getting the establishment of state health departments and that some progress was being made. However, there was already misunderstanding among the medical profession as to the significance of the term "state medicine" so that the committee said:

> As the phrase "State Medicine" is perhaps imperfectly understood by many of the profession, and is absolutely new to the general public, we wish here, parenthetically, to give an idea of what it is, quote the list of subjects which have been suggested as properly appertaining to it by a committee of the General Medical Council of Great Britain. They are: Forensic Medicine, Toxicology, Morbid Anatomy, Psychological Medicine, Laws of Evidence, Preventive Medicine, Vital and Sanitary Statistics, Medical Topography and certain portions of Engineering Science and Practice. In short, as a member of the committee well expresses it, State Medicine consists in the application of medical knowledge and skill to the benefit of communities, which is obviously a very different thing from their application to the benefit of individuals in private or curative medicine.

The concluding action of this committee was to ask that it be continued and that a special section on state medicine and public hygiene be constituted as one of the scientific sections of the Association.

The Committee on Ethics reaffirmed its previous actions relative to the refusal to admit the Freedman Hospital, the Howard University and the Academy of Medicine of Washington, D. C., to representation because some of the members of their staff were unlicensed and because one of the teachers in Howard University was a woman. The battle over the status of the physicians, the societies and the schools in the District of Columbia was fiercely fought on the floor of the convention. At the end of the extensive discussions, the report of the Committee on Ethics barring the representatives from these agencies was adopted by a large majority.

Again the delegates besought the Congress of the United States to give some attention to the cultivation of the cinchona tree, pointing out that the British and the Dutch were hard at work on this project, but apparently Congress refused to take any action.

THE PERMANENT SECRETARY

Now there arose the delicate question of the remuneration of the permanent secretary, Dr. William B. Atkinson. His duties had become more engrossing every year with the growth of the Association and his remuneration was nil. Therefore the resolution was offered that he be paid a salary of $1,000 a year in quarterly payments, and the session unanimously resolved to present him with $500 as a testimonial to his merit.

An attempt was made to get through a resolution upholding Horace Wells as the discoverer of anesthesia, and the resolution was laid on the table. As late as 1946 this question was again before the Association and again it was tabled.

Another resolution suggested that "whilst we admit the right of women to acquire medical education and to practice medicine and surgery in all their departments, we deem the public association of the sexes in our medical schools and at the mixed clinics of our hospitals, as impracticable, unnecessary, and derogatory to the instincts of true modesty in either sex." This resolution was also laid on the table. After a while a resolution was made to take it off the table, and after some more discussion it was indefinitely postponed.

The President of the Association, Dr. D. W. Yandell, presented a strong defense of the right of women to practice medicine but he would have limited them to certain specialties. He trusted that not many would incline to surgery, but he thought that they would be welcome visitors to many a sick chamber. "If young and handsome," he said, "I have no doubt valetudinarians of our sex would look for their morning calls as they might for angel visits, only that they would not have them 'short and far between.'" He felt that the public should really make the decision on the use of women physicians and he concluded this part of his discussion by saying:

> What the people decree in this matter is a law to which all, we and the women alike, must bow submissively. If they want women doctors, such will be found ready to meet the demand. If those now pressing forward in their studies so eagerly, find their services are not wanted, they will take down their signs, get married—if they can—or turn lecturers, or to some more lucrative employment. I hope they will never embarrass us by a personal application for seats in this Association. I could not vote for that.

1873

ST. LOUIS

Most significant of the business before the Association's meeting in 1873 was the report of the special committee to plan for better arrangements by the sections for the more rigid examination of papers offered for publication. A few of the sections were receiving maximum attendance but a few listeners. A reorganization was suggested. The Committee of Publications was not doing a good job in rejecting unworthy manuscripts and was condemned for its failure to be more strict. That perhaps explains the skimpiness of the volume of Transactions for that year.

THE JUDICIAL COUNCIL

This year saw also a resolution offered by Dr. N. S. Davis for the creation of a judicial council to decide all questions of an ethical or judicial character that might arise in connection with the Association. His resolution was unanimously adopted.

From the Army came a request that the Association join its efforts to obtaining better ranks and higher promotions for the medical officers of the Army.

DISINTEREST IN NOMENCLATURE

The committee on nomenclature reported that not a single response had been received from any medical journal, and only two from physicians, to the request for the circularization of the nomenclature.

A long report dealt with the proposed salary of $1,000 a year for the permanent secretary. The committee felt that the secretary was already receiving payment of his expenses in attendance on the conventions; they felt that the revenue of the Association was inadequate to meet a salary of $1,000 a year and that, furthermore, the payment of the salary of $500 to $1,000 a year would speedily develop a number of aspirants for the position, each with his circle of friends among the members, all of whom would be quick to perceive the errors and to note the slightest tardiness or discourtesy on the part of the incumbent of the office, and that this job would be sought as a political plum. The suggestion of a salary was therefore rejected, but a motion that he be given an honorarium was approved, provided sufficient money was left in the treasury after paying the expenses of the Association.

The meeting closed with a number of resolutions condemning the alarming prevalence of ill effects of intemperance. The resolutions were either tabled or referred to committees.

1874

DETROIT

The second annual session of the Association to take place in Detroit abandoned the Fire House and moved into Hough's Detroit Theatre. Detroit had grown in the intervening years from a city of 40,000 to one of 100,000 inhabitants.

The speech of welcome was a glorification of the growth of this great industrial city and of its new city hall (erected at a cost of $600,000), from whose dome not only the city but Lake Erie was visible. The speaker boasted of the excellent sewerage system, the public school system (due chiefly to Dr. Pitcher), the public library and the police and fire departments.

THE PRINCIPLES OF ETHICS

Significant was the introduction of a report by Dr. N. S. Davis of Illinois, chairman of the Judicial Council, who had ascertained the sentiments of the physicians relative to revisions in the Principles of Ethics. It had been proposed to strike out everything having to do with the relations of the patient, the community and the public toward the members of the profession. It was felt that there ought to be more said about specialties and contract practice. After carefully reviewing the entire subject, the committee did not recommend any alteration in the Code of Ethics but desired "to express the opinion that if every medical school and society would supply each graduate as he left the school, and each member initiated into the society, with a printed copy of the Code, accompanied with the injunction that it be carefully studied, it would be productive of much good, directly to the profession and indirectly to the community." The report was unanimously adopted.

As a result of the pressure brought by the Association a bill had been introduced into the Congress relative to improved status for the medical staff of the Army. The bill had been introduced and referred to the military committee, which however had failed to take action. A resolution was therefore adopted regarding this failure to take action and sent along to the Congress.

INDEX CATALOGUE OF THE SURGEON GENERAL'S LIBRARY

Now also Dr. John Shaw Billings, assistant surgeon, United States Army, by direction of the Surgeon General forwarded to the American Medical Association a copy of the "Catalogue of the Surgeon General's Office" in three volumes. He called attention to the fact that 65,000 titles were now in the library but that this was not more than one third of what the national medical collection should contain. It was proposed to issue a new catalogue arranged according to subjects and authors. He urged physicians everywhere to send to the library files of American medical journals, transactions of medical societies, announcements of medical colleges and reports of hospitals, asylums and boards of health. "These medical pamphlets," he said, "cannot be purchased and the only prospect of obtaining them is from the garrets, closets and shelves of physicians who may have preserved them and may be willing to part with them in consideration of the object for which they are desired."

The address of the President, Dr. Joseph M. Toner, made several recommendations which stimulated action in the Association. He urged particularly the formation of a complete system of state and local medical societies and also of an international medical society.

Because the centennial of the founding of the United States was to be celebrated in Philadelphia in 1876, an invitation came from that city to hold the annual session of the American Medical Association in Philadelphia on July 4, 1876 and to invite the medical profession of the world to attend the meetings.

A resolution was passed that a suitable die for a medal be prepared with a likeness of N. S. Davis on one side and the name and date of the organization of the Association on the opposite side, with instructions that a copy be furnished to each delegate on becoming a member and also that all present as well as future members of the Association be furnished with this medal.

A motion was made to recompense the secretary with $300 for his services. On motion of J. Marion Sims of New York, this was increased to $500. The motion was seconded and adopted.

The treasurer of the Association was glad to report that "as a result of more than usual discretion on the part of the last meeting of the Association, and the more than usual care exercised in referring matter to the Committee of Publication, the volume of Transactions is of moderate size." Because of a lack of demand, there had accumulated some 2,000 volumes of previous issues of the Transactions and the treasurer moved that he be allowed to dispose of these. With this suggestion, Dr. Caspar Wistar, the treasurer, offered his resignation.

A resolution was offered by Dr. Keller of Kentucky that a committee be established relative to passing proper legislation to prevent the spread of syphilis.

ADVANCES IN DIAGNOSTIC METHODS

In his presidential address Dr. Joseph Toner called attention to the beginning of laboratory and other technical methods used in the diagnosis and treatment of disease. He said:

> The successful medical man must be fully up with the age and the times, conversant with the latest means of diagnosis, the theory of diseases and their cures. He must have tested the newest remedy, examined the most recent invention; he must have read the latest telegram. And, indeed, the genius of the profession, responding to these demands, has devised physical tests for an exact diagnosis in almost every important disease. There is scarcely a vital function the normal or diseased action of which cannot be determined with accuracy through the aid of some chemical test or mechanical device.[1] The improvement in this direction is still actively progressing.

He called on the medical profession to urge particularly more state, county and city boards of health.

SYPHILIS

The address in surgery was delivered by S. D. Gross and was entitled "Syphilis in Its Relation to the National Health." He said that the assertion that syphilis originated in the new world and was carried back by the sailors of Columbus is without the slightest foundation in truth but, instead, that the sailors of Columbus had infected the natives. While this belief is still subject to some argument today, the vast majority of evidence inclines to the former view. His address was nevertheless a most scholarly presentation of the available knowledge of his day concerning this disease. He urged as the only possible technic for preventing its spread, the licensure of prostitution. He was a little ahead of his time in urging that people should not be allowed to marry until they could obtain a certificate showing that they did not have syphilis—but, of course, at that time there were no accurate tests of the presence of the disease such as the Wassermann and Kahn tests used today.

Clinical Notes, Suggestions and New Instruments

CONVULSIVE SEIZURES FOLLOWING BARBITURATE WITHDRAWAL

CARROLL W. OSGOOD, M.D.
Wauwatosa, Wis.

Despite the well recognized hazards of injudicious use of barbiturates, the controlled employment of these drugs in the care of institutionalized patients has in my experience been safe and effective. Seldom has a sustained increase in dosage been necessary, such as would point to development of tolerance; and most patients, with improvement or recovery, have lost their insomnia and have been able to discontinue hypnotics with little difficulty. Nevertheless, observations over the past fourteen years at a private sanatorium for the treatment of nervous and mental disorders show the infrequent occurrence of withdrawal symptoms. Similar observations have been reported in the psychiatric literature [1] but seem not to have gained wide attention. General discussions of the barbiturate "problem" [2] have failed to mention the symptoms about to be described.

Six patients at the sanatorium have had from one to three convulsive seizures following reduction or discontinuance of barbiturates. None of these had a previous history of seizures [3] and none had subsequent seizures during his time in the hospital or later, as far as is known to me. While previously reported seizures [1] have followed complete and sudden withdrawal of the drug, 4 of the 6 patients mentioned herein had convulsions in the course of gradual withdrawal. Three additional patients gave a history of seizures following the withdrawl of barbiturates prior to coming to the sanatorium, and 2 other instances from private practice have been brought to my attention.[4] Available data on patients seen at the sanatorium are given in the accompanying table.

[3] Except 1 associated with barbiturate withdrawal.

[4] (*a*) Howard, M. Q.: Personal communication to the author. (*b*) Belknap, E. L.: *ibid.*

Most of the patients here mentioned had gradually increased their consumption of barbiturates to much larger than average dosages and had continued it over periods of months or years. One convulsion occurred during reduction of sodium amytal following prolonged therapeutic sleep. While none of the convulsions has had any subsequent ill effect on the patient, these seizures have created a fear of possible idiopathic epilepsy or of some organic brain lesion and have caused concern to the patients, their relatives and their physicians. Knowledge of the possibility of this reaction as a result of barbiturate reduction or withdrawal is thus of importance in differential diagnosis. In 1 instance reported to me [3a] the occurrence of convulsions served to clinch the diagnosis of suspected barbiturate addiction in a woman who had previously denied it and whose husband was unaware of it. The manifestation is of interest, also, in confirming the existence of true physiologic addiction to barbiturate compounds.

Milwaukee Sanitarium, Wauwatosa 13.

Data on Convulsive Seizures Following the Withdrawal of Barbiturates

Case	Sex	Drug	Daily Dose		Duration	Reduction at Time of Convulsion	Number of Convulsions	Day of Convulsion After Reduction Begun	Comment
			Grains	Gm.					
1. H. F. R.	♂	Neonal sodium Phenobarbital	18 1½	1.16 0.1	3 yrs.	To 6 grains (0.39 Gm.) sodium amytal	1	2d	Enlarged liver, myocardial degeneration; age 77
2. C. A.	♀	Pentobarbital sodium	18-21	1.16-1.55	2 mos.	To ?	3 in one day	?	History only of these convulsions; occurred prior to admission
		Pentobarbital sodium	12	0.78	3½ mos.	To 9 grains (0.58 Gm.)	2	2d and 5th	These convulsions while in sanatorium
3. O. E. L.	♂	Seconal sodium Phenobarbital	9 2	0.58 0.13	1½-2 yrs.	Seconal sodium to 3¾ grains (0.24 Gm.) Phenobarbital to 0	1	3d	Wife had noted rare spells (during period of barbiturate consumption) when patient was unresponsive and eyes rolled
4. W. H.	♂	Pentobarbital sodium	?		Several months	To 0 (abrupt withdrawal)	1	3d	
5. R. B. S.	♀	Sodium amytal	48	3.11	2 wks.	To 9 grains (0.58 Gm.)	1	4th	In course of prolonged therapeutic sleep
6. B. D.	♀	Sodium amytal	15	0.97	Several months	To 3 grains (0.19 Gm.) for 7 days. To 0 for 1 day	1	8th	On diphenylhydantoin sodium 1½ grains (0.1 Gm.) daily from time of reduction; had had electroshock therapy 2 years previously
7. R. T. R.	♀	Seconal sodium	9	0.58	5 yrs.	To ?	2	?	History only of these convulsions; occurred before admission
8. S. R. E.	♂	Pentobarbital sodium	Up to 27	1.75	2+ yrs.	To ?	1	?	History only of these convulsions; occurred before admission
9. V. A. M.	♀	Phenobarbital Seconal sodium	? 15-18	 0.97-1.16	5 yrs.	To 0 (abrupt withdrawal)	5	?	History only of these convulsions; occurred before admission; delirious 5 days after convulsions

CHRONIC PORPHYRIA COMPLICATED BY PREGNANCY

SIDNEY LINAS, M.D.; MILTON L. SOLOMON, M.D.
and
FRANK H. J. FIGGE, Ph.D.
Baltimore

Since there does not appear to be a case of chronic porphyria complicated by pregnancy reported in the literature, it was felt advisable to report a case which has recently been under our care. A preliminary report of this case was made by Taylor, Solomon, Weiland and Figge.[1]

REPORT OF CASE

History.—A white, married woman, aged 20, a native of Baltimore, was hospitalized several months prior to her pregnancy. At that time the diagnosis of chronic porphyria was definitely established. A full report on the history, physical examination, hospital course and progress of this patient appears in the previously cited article.

She was advised against becoming pregnant because of the unknown influence that pregnancy might have on the prognosis of the porphyria and because some types of porphyria appear to be inheritable. However, she apparently disregarded the advice, and in June 1945 she presented herself, at which time she was about two months pregnant. Her last menstrual period had occurred on April 20, 1945, making the estimated date of confinement Jan. 27, 1946. This patient was a primigravida and had been married for fifteen months.

Physical Examination.—The patient was a well developed and well nourished woman with a normal appearance except for cutaneous lesions. Her height was 5 feet 3 inches (160 cm.) and her weight 120 pounds (54.6 Kg.). Her nonpregnant weight was about 116 pounds (52.6 Kg.). Pelvic measurements were essentially normal. Vaginal examination revealed the uterus about the size of a six weeks pregnancy. The only positive observations on examination were the lesions of the skin that the patient exhibited. There were numerous vesicles on the hands and arms and some on the neck. Scattered over the arms, legs, neck and face were small, almost undetectable, brownish pigmented pockmarks from her earlier cutaneous lesions. At this time the patient was on the following treatment regimen: calcium lactate 40 grains (2.6 Gm.), sodium bicarbonate 80 grains (5.2 Gm.) and riboflavin 40 mg. by mouth daily. She also was receiving one ampule of Solu B[2] intramuscularly three times a week and 1 cc. of liver extract (15 U. S. P. units) intramuscularly once a week.

Course and Treatment.—The patient seemed somewhat improved in June 1945, and the administration of Solu B and liver extract was discontinued for one month. Obstetrically, the pregnancy progressed normally, but in July 1945 she began to show a decided exacerbation and extension of the cutaneous lesions. New lesions appeared on the arms, legs, neck and face (exposed surfaces).

Intense itching was present, and some of the lesions were secondarily infected, apparently from scratching. There was pronounced edema of the ankles, and she complained of frequent cramps throughout both legs.

Aided by grants from the Anna Fuller Fund and the Donner Foundation.

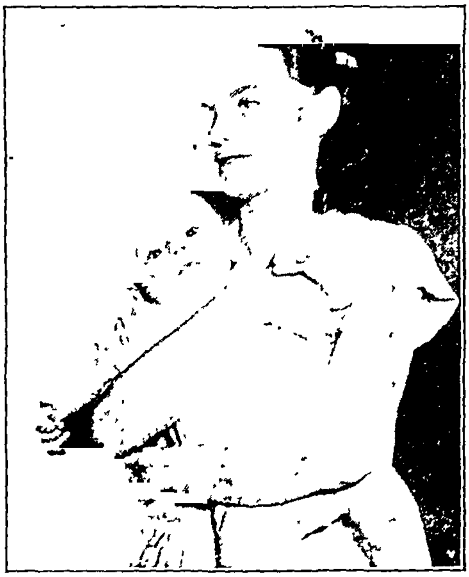
From the West Baltimore General Hospital and the University of Maryland School of Medicine.

[1] Taylor, I. J.; Solomon, M. L.; Weiland, G. S., and Figge, F. J. H.: Chronic Porphyria, J. A. M. A. **131:** 26 (May 4) 1946.

[2] Solu B (The Upjohn Company) is a mixture of thiamine hydrochloride 10 mg., riboflavin 10 mg., pyridoxine hydrochloride 5 mg., calcium pantothenate 50 mg. and nicotinamide 250 mg. in powder form for injection after proper solution has been effected.

By August 1945 the lesions of the skin were much worse and showed more extensive infection, in spite of the previously mentioned therapy and in addition, the use of a skin lotion containing tannic acid, the avoidance of exposure to sunlight and the constant wearing of black clothes. (See photograph in previous report.[1]) Because of the progression of the lesions and the hypothetic possibility of transmission of the disease to the offspring through heredity, interruption of the pregnancy at this point was seriously considered and discussed. In view of the fact that the relationship of pregnancy to chronic porphyria was unknown, and since the strict adherence of the patient to the treatment regimen and the advice given was questioned, it was decided to intensify the treatment and to carry on the pregnancy as far as possible, with the patient under extremely close observation.

When the original porphyrin determinations were made, the patient had been excreting 1,200 to 1,600 micrograms of porphyrin a day. This rate of excretion was continued for almost a year, though it had dropped to approximately 800 to 1,000 micrograms a day with therapy. It increased again during pregnancy to 1,200 micrograms in August 1945. At this time the following therapeutic schedule was established: calcium lactate 40 grains (2.6 Gm.) and sodium bicarbonate 80 grains (5.2 Gm.) by mouth daily. She also received riboflavin 20 mg. every four hours, ascorbic acid 1,000 mg. every four hours and nicotinamide 100 mg. twice daily orally. The intramuscular injection of liver extract was discontinued, and she was given one ampule of Solu B intramuscularly twice weekly. An ointment containing penicillin was used for the lesions of the skin.



Patient on June 27, 1946 showing much improvement of cutaneous lesions. (Compare with photograph in previous report.[1])

The patient felt subjectively better on this regimen, but new lesions continued to appear while the old ones were healing and leaving pigmented areas. This condition continued throughout the remainder of pregnancy. The lesions became secondarily infected from scratching and healed slowly. The penicillin afforded some relief.

In December 1945 she showed a moderate, diffuse, soft enlargement of the thyroid without nodules that could be palpated. Thyrotoxic signs were not present. Her pulse rate remained at 80 to 86 per minute. The blood pressure was 110 to 120 mm. of mercury systolic and 60 to 80 mm. of mercury diastolic. The pregnancy progressed entirely uneventfully except for a slightly excessive gain in weight, a total of 36 pounds (16.6 Kg.). Urinalysis remained negative for albumin and sugar. At the end of pregnancy the patient was still excreting 1,200 micrograms of porphyrin a day.

The patient went into labor spontaneously on Jan. 30, 1946. Labor progressed normally. Seconal sodium and meperidine hydrochloride (Demerol hydrochloride) were used for analgesia. Artificial puncture of the membranes was performed in order to obtain amniotic fluid for study. This fluid was darker than could be accounted for by the small amount of meconium present in it. It contained large amounts of porphyrin, but this was not determined quantitatively because normal amniotic fluid contains high concentrations of coproporphyrin I. This is thought to arise from meconium and varies greatly in different cases. After a total labor of nineteen hours and five minutes, the patient was delivered of a live male child under gas-oxygen-ether anesthesia by low forceps from the right occipito-anterior position after a preliminary mediolateral episiotomy. The baby cried after one minute of mild resuscitation and appeared to be normal. The placenta separated spontaneously and showed fairly extensive diffuse fibrosis. The placenta contained many calcareous deposits which were brilliantly red fluorescent under near ultraviolet light.

The puerperium was entirely afebrile. All medication was discontinued on admission to the hospital. The only medication the patient received subsequent to delivery was ergonovine maleate $\frac{1}{320}$ grain (0.0002 Gm.) every four hours for twenty-four hours and ferrous sulfate 5 grains (0.324 Gm.) three times a day by mouth. Within forty-eight hours after delivery the lesions on the face and neck showed much improvement. The remaining lesions began slowly to regress and dry up, leaving brownish pigmented areas. The milk was examined spectroscopically at this time, and coproporphyrin was found to be present, but the amount of milk available was too small for a quantitative determination.

The baby was not allowed to be breast fed since it was considered advisable to eliminate this source of porphyrin and also to supply the mother with as much rest as possible. The child weighed 7 pounds 15½ ounces (3,614 Gm.) at birth and 7 pounds 5 ounces (3,317 Gm.) on discharge from the hospital. The urine of the baby was collected for the first three days after birth. This collected specimen contained sufficient porphyrin to be evident spectroscopically and to form a red fluorescent precipitate. This disappeared by the third day.

Mother and baby were discharged from the hospital on Feb. 8, 1946.

Laboratory Observations.—Examination of the blood on Jan. 31, 1946 showed a hemoglobin of 62 per cent. On Feb. 1, 1946 examination of the blood revealed 70 per cent hemoglobin with a red cell count of 3,810,000 and a white cell count of 13,900 with 72 per cent neutrophils, 20 per cent lymphocytes, 2 per cent monocytes, 2 per cent eosinophils and 4 per cent stab forms. The blood cholesterol was 220 mg. per hundred cubic centimeters. The icterus index was 5 and the direct and indirect van den Bergh reaction was negative. Other determinations on the blood showed: uric acid 3 mg., urea nitrogen 15 mg., urea 32.1 mg. and serum calcium 10.5 mg. per hundred cubic centimeters. The total protein was 7.15 Gm., the albumin 4.4 Gm., and the globulin 2.75 Gm. per hundred cubic centimeters of blood, making a ratio of 1.6. The Eagle flocculation test was negative; the cephalin was 1 plus. The sulfobromophthalein test revealed 2 per cent retention with 5 mg. of the dye per kilogram of body weight, a blood sample being withdrawn in forty-five minutes.

Subsequent Course.—Since discharge from the hospital the patient has continued to show subjective and objective improvement. The majority of the cutaneous lesions have cleared but have left brownish, pigmented, scarred areas. At the present time she is approximately seven months post partum and has not shown exacerbations of the porphyria. New lesions have appeared from time to time on the exposed surfaces of the skin when the patient is exposed to bright sunlight, but these lesions have been few in number and clear up rapidly. The patient has learned to avoid bright sunlight as much as possible. The only medicament which she has received since delivery, and which she is still taking at the present time, has been ferrous sulfate 10 grains (0.65 Gm.) three times a day. She has carried on her daily household duties in normal fashion; she feels and looks well. The baby has developed normally and has shown no evidence of porphyria. Examination of the patient's urine at three intervals since the birth of the child shows that the porphyria has progressively decreased until at present she is excreting about 400 micrograms of urinary porphyrin a day. This is approximately four times the normal amount.

SUMMARY

A case of chronic porphyria complicated by pregnancy in a woman aged 20 has been presented. During pregnancy there was an exacerbation of her cutaneous lesions and porphyrin excretion, both of which improved rapidly after delivery. The pregnancy was unaffected by the chronic porphyria, and the offspring seems normal as far as can be determined. We would like to be able to make a definite statement in regard to the effect of pregnancy on chronic porphyria, but from our observation in the reported case we cannot definitely say that pregnancy is or is not harmful to the patient with chronic porphyria. The spectacular improvement which started immediately post partum and which has continued for several months makes it appear that the total experience has had a beneficial influence on the patient. This, and the fact that the child appears perfectly normal, would lead one to the conclusion that chronic porphyria is not an indication for the interruption of pregnancy.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement.

Austin Smith, M.D., *Secretary*.

THE STATUS OF METHIONINE IN THE PREVENTION AND TREATMENT OF LIVER INJURY

A manufacturer has presented a brand of methionine to the Council for inclusion in New and Nonofficial Remedies. The conditions for which methionine has been reported to be beneficial include its use in the prevention and treatment of liver injury due to poisonous agents such as arsenic, chloroform, carbon tetrachloride and trinitrotoluene. In addition, the use of methionine has been recommended in the treatment of eclampsia, shock, infectious hepatitis and cirrhosis of the liver. The Council has reviewed the available evidence with regard to the value of methionine in these conditions and feels that, although this drug offers some therapeutic promise, further work is necessary before the claims of the manufacturers may be considered to be established.

Various investigators[1] have presented evidence based on animal experiments that liver injury, particularly fatty infiltration, may be produced by dietary deficiencies. Best and Rideout[2] suggested choline as the necessary constituent of the diet to prevent fatty changes of the liver.

Certain chemical agents produce pathologic lesions in the livers of experimental animals closely resembling those seen in human beings with portal cirrhosis. Miller, Ross and Whipple[3] reported that either methionine or cystine would protect dogs against liver damage produced by chloroform. György and Goldblatt,[4] on the other hand, showed that in rats on a low protein diet necrosis or cirrhosis of the liver would develop which could be partially prevented by administration of choline but which was accentuated by the feeding of cystine. Addition of choline or yeast to the cystine diet prevented the liver changes.

Daft, Sebrell and Lillie[5] confirmed the work of György and Goldblatt and found that some protection to the livers of their animals was afforded by addition of choline, methionine and casein. It was concluded by György and Goldblatt[6] that the cirrhosis produced in animals by a low protein diet could be prevented by a combination of choline and cystine or by methionine alone.

Drill and Loomis[7] have shown that methionine feeding does not decrease the liver damage resulting from carbon tetrachloride poisoning in dogs maintained on a normal protein intake of 20 per cent or 41 per cent casein. In protein-depleted dogs methionine appeared to be responsible for a decrease in the degree of liver damage following carbon tetrachloride poisoning.

It is to be emphasized, however, that the dietary cirrhosis seen in animals is not histologically the same as portal cirrhosis in man[8] and that the animal experiments discussed here, while encouraging, need clinical confirmation by carefully controlled investigations on human patients.

Methionine has been used in the treatment of "postarsenical" liver damage with equivocal results. Beattie and Marshall[9] reported that methionine and cystine would protect patients against liver damage due to arsphenamine; however, critical examination of their data shows that, although the onset may have been delayed slightly by the treatment, the patients did have liver damage. The experiments were inadequately controlled and have been criticized by Peters and his associates.[10]

There is no evidence for the value of methionine in eclampsia. A thesis by Rinehart[11] suggests, but does not prove, that this toxemia may be associated with inadequate protein intake. On the basis of this thesis the manufacturers who presented methionine to the Council have suggested that this amino acid will prevent eclamptogenic toxemia.

The clinical evidence for the usefulness of methionine in the treatment of liver injury due to chloroform, carbon tetrachloride and trinitrotoluene is on slightly firmer ground. Beattie and his associates[12] reported 1 case of acute carbon tetrachloride poisoning in which recovery appeared to be influenced by massive doses of methionine. Eddy[13] has reported a few cases of carbon tetrachloride poisoning treated with a high protein, low fat diet plus 6 to 12 Gm. of methionine daily. No control observations were made, and it is not possible to attribute the beneficial results to the administration of methionine alone, since the diet used is known to have a beneficial action. The same criticism may be made of Eddy's later report[14] on methionine treatment of trinitrotoluene poisoning.

Peters and Croft[15] have suggested the use of methionine for patients with severe burns, since it is known that liver damage frequently occurs in such instances. However, no clinical investigations were reported and their conclusions were based on partially controlled animal experiments.

Although the manufacturers of methionine suggest its use in the treatment of infectious hepatitis, Wilson, Pollock and Harris[16] reported no significant effect on the severity or duration of the disease in patients treated with methionine. A member of the Council who had extensive experience with methionine and infectious hepatitis in the recent war also points out that methionine could not be demonstrated to affect the course of the disease.

The paucity of controlled clinical evidence on the value of methionine in the treatment or prevention of liver injury leads the Council to the conclusion that no claims for this product may be recognized at this time; but in view of the encouraging animal experiments, careful clinical trial of this agent by competent investigators should be made. Until further convincing evidence of the usefulness of methionine in liver disease is available, the Council has deferred acceptance of brands for inclusion in New and Nonofficial Remedies.

SATURDAY, JANUARY 11, 1947

DEATHS OF PHYSICIANS IN 1946

The obituaries of 3,358 physicians were published in The Journal during 1946. The American Medical Directory Report Service recorded 3,312 deaths in the United States, possessions and temporary foreign. In addition approximately 200 notices of deaths had been received but not yet published, giving a total of 3,558 for general consideration. The present analysis, however, is concerned only with the 3,358 deaths published.

Age.—The average age at death was 66.1 years as compared with 65.3 in 1945. Five physicians died between the ages of 20 and 24, 43 between 25 and 29, 70 between 30 and 34, 99 between 35 and 39, 111 between 40 and 44, 132 between 45 and 49, 169 between 50 and 54, 283 between 55 and 59, 377 between 60 and 64, 525 between 65 and 69, 584 between 70 and 74, 452 between 75 and 79, 290 between 80 and 84, 158 between 85 and 89, 50 between 90 and 94 and 6 between 95 and 99, and of the 4 who had reached 100, 1 was 105 years of age.

Causes.—Heart disease remains the leading cause of death among physicians. With primary causes and contributory factors included in the general statistics, coronary thrombosis and occlusion led the heart group with a total of 738; 283 deaths occurred in the ages between 60 and 69. Diseases of the myocardium and pericardium accounted for 123 deaths, angina pectoris and other coronary diseases 106, chronic valvular and rheumatic heart diseases 28, subacute bacterial endocarditis (except rheumatic fever) 7 and other diseases of the heart 375.

Cerebral hemorrhage, thrombosis and embolism accounted for 404 deaths, arteriosclerosis for 185 and cardiovascular diseases for 91. Cancer and tumors were responsible for 352 deaths, 143 of which were classified under cancer of the gastrointestinal tract. Of 199 deaths ascribed to pneumonia, 13 were due to atypical or virus pneumonia. Tuberculosis caused 31 deaths, asthma 10, bronchitis and pleurisy 5, and other diseases of the respiratory system 31. Chronic nephritis and uremia accounted for 111 deaths and acute nephritis for 12. Diseases of the circulatory system caused 72 deaths, diabetes 46, cirrhosis of the liver 35 and other diseases of the liver 3, Hodgkin's disease and leukemia 32 and other diseases of the blood 9, diseases of the nervous system 27, diseases of the prostate 21, pulmonary embolism and thrombosis 19, peptic ulcer (ulcer of the stomach and duodenum) 16, aneurysm 13, influenza 12, diseases of the gallbladder, bile duct and cholecystitis 11, diseases of the spinal cord and peritonitis 10 each, appendicitis 6, diseases of the brain 5, encephalitis, meningitis, pernicious anemia and chronic arthritis 4 each, hernia, mental disease, syphilis, abscess, other infectious diseases, diseases of the bones and organs of locomotion and diseases of the skin 3 each, bacteremia, septicemia and pyemia, alcoholism and epidemic hepatitis 3 each, amebic dysentery 2, and rheumatic fever, poliomyelitis and trichinosis 1 each. Twenty-one deaths followed an operation. Senility was returned as the cause in 29 instances, while the cause of death was ill defined in 7. There were 62 deaths for which the cause was not obtained.

Suicides and Homicides.—Significant is the total of 55 suicides as compared with the 25 recorded for 1945. Twenty-four were attributed to bullet wounds, 9 to drugs, 5 each to cut arteries and poison, 2 each to jumping, illuminating gas, hanging and strangulation, and 1 each to drowning and monoxide gas. The method was not reported in 1 death, and 1 physician threw himself under a train. Of the 6 homicides shooting was the method used in 5, and 1 physician died of injuries received when struck by the husband of a patient.

Accidental Deaths.—Of the 130 accidental deaths, automobiles were involved in 55. One automobile accident occurred in a collision with a train and 1 with a street car. Four deaths were attributed to x-ray accidents and complications. Of the unusual accidents 1 physician was killed by a bolt of lightning while playing golf, 1 of injuries received when he fell under the wheels of a mule drawn wagon, 1 when a tractor he was driving overturned and 1 when a broken power cable wire struck him over the head; 1 died in the La Salle Hotel fire.

Miscellaneous Positions.—Among the decedents were 274 who had been teachers in medical schools, of whom 122 had reached professorial status. There were 7 deans, 1 president of a high school, 1 vice president of a medical school, 1 teacher in a public school and 122 members of education boards. One hundred and sixty-nine had been health officers, 108 members of boards of health, 67 coroners, 51 mayors, 31 authors, 29 members of medical examining boards, 27 bank presidents, 27 legislators, 26 pharmacists, 16 editors, 12 missionaries, 8 dentists, 7 postmasters, 4 lawyers and 3 interns. Four physicians had served with the fire department and 8 with the police department. One had been deputy collector of internal revenue, 1 city treasurer, 1 state health officer, 1 state commissioner of labor, 1 a Danish vice consul, 1 a vice consul at the Turkish capital, 1 a member of the Civil Service Board, 1 minister to Ecuador and 1 trustee of a college. Of the miscellaneous group 2 had been in the Boer War, 1 in the Boxer Rebellion, 2 in the Philippine Insurrection and 47 in the Spanish-American War. Five hundred and fifty had served during World War I, 2 each with the British navy and army, 2 with the Canadian army, 2 in the Russian imperial army and 1 each in the British Expeditionary Forces and the armies of France, Italy and Poland.

Association Officers.—Included among the decedents were 1 who had been Vice President of the American Medical Association, 1 charter member of a council, 4 chairmen of councils and 13 section officers. Thirty-four had been members of the House of Delegates and 1 Speaker of the House. There were 35 presidents of state medical societies, 4 secretaries of state societies and 216 who had been presidents of county medical societies.

Killed in Action

The 3,358 obituaries included 40 physicians who were killed in action during World War II and 128 who died while in military service. A number of those who were killed in action had first been reported missing in action. The following locations as those where injuries resulting in death occurred as noted in official reports: Asiatic area 8, Philippine Islands 7, China Sea 6, Germany 5, Pacific area 5, Italy 2, France 2 and 1 each at Formosa, Luzon, North African area, Okinawa and Tinian. Nine were reported as prisoners of war, and 1 was killed when a Japanese suicide plane crashed into an auxiliary hospital transport. Eleven died at ages between 25 and 29, 9 between 30 and 34, 13 between 35 and 39, 2 between 40 and 44, 3 between 45 and 49, 1 between 50 and 54, and 1 between 55 and 59.

Died While in Military Service

Of the 128 physicians who died while in military service, coronary thrombosis caused 19 of the 29 deaths attributed to various forms of heart disease. Airplane accidents caused 16 deaths and automobile accidents 9. Cancer was responsible for 10 deaths, 3 of which were brain tumors. The remaining deaths from miscellaneous causes included 1 from poliomyelitis, 1 from tsutsugamushi fever and 2 each from acute infectious hepatitis and spinal meningitis. One physician died following an operation, and causes were not obtained in 10 deaths. Gunshot wounds led the suicides with 8 deaths, poison 2 and illuminating gas, hanging and stab wound of the chest 1 each. Two died between the ages of 20 and 24, 17 between 25 and 29, 28 between 30 and 34, 29 between 35 and 39, 25 between 40 and 44, 10 between 45 and 49, 9 between 50 and 54, 3 between 55 and 59, 4 between 60 and 64, and 1 between 65 and 69.

Of the 5 U. S. Public Health Service officers included in the general group of 3,358 deaths, 1 aged 39 was killed in action in the China Sea, and 1 aged 37 died of avitaminosis in Japan while a prisoner of war.

The 40 deaths classified as killed in action give an average age of 35.2, while the average for the 128 who died while in military service is 42.8. Combining the two, an average of 37.7 is recorded. Deducting this group from the general total of 3,358, an average of 67.5 is reached. Caution should be exercised in the interpretation of these figures, since a number of these young physicians would have died from other causes had they remained in civilian life.

Since the outbreak of World War II on Dec. 7, 1941 The Journal has recorded the deaths of 257 physicians who were killed in action and 501 who died while in military service. Reports still being received by The Journal indicate that the aggregate total of 758 military deaths among physicians will be greatly augmented when the complete statistics are made available through official military channels.

A NEW SURVEY OF MEDICAL EDUCATION

On recommendation of the Council on Medical Education and Hospitals of the American Medical Association, the Board of Trustees has authorized a new complete survey of the medical schools. The American Medical Association will undertake the entire financial responsibility for the survey. However, a collaborative effort with the Association of American Medical Colleges and the individual colleges is planned, so that the project can achieve the end of improved medical education in this country.

Ten years have passed since the last previous complete survey was made, under the direction of H. G. Weiskotten, now chairman of the Council. In the meantime there have been tremendous impacts on the entire structure of medical education, during the troubled war years and in the present era of reconversion to peacetime education. In the light of recent advances in medical knowledge and the nature of medical care a careful reevaluation of the curriculum is needed. Financially many schools are facing a crisis, since the increased income of the war years will be drastically reduced unless supplemented by funds from endowment, state or other sources. There is need for a thoroughgoing analysis of the educational resources of our medical schools as related to student enrolments.

Much general attention has been given to the two major surveys of the past: that of Abraham Flexner nearly forty years ago, and that of H. G. Weiskotten a decade ago. Yet the program of surveying individual medical schools and assisting them to improve has gone on year after year under the auspices of the Council and the Association of American Medical Colleges. Valuable though this continuous program has been, it must be supplemented at opportune times by complete surveys of all schools.

The aim of the survey will be that which has motivated every activity of the Council in the past: to improve medical education and to render all assistance to medical schools to improve themselves, so that the quality of medical care in this country will continue to improve and the position of world leadership in medical education occupied by the schools of this country will be maintained and strengthened.

MORE NURSES NEEDED

Physicians need not be told that there is a "nurse shortage." Although more professional nurses are available today in the United States than at any time in the past, the supply has not been able to meet the demand. The National Nursing Council's Committee on Statistical Research estimates the deficit in August 1946 as 41,000.

A large proportion of this year's graduates have indicated that they expect to take hospital positions. The student nurses enrolled under the U. S. Cadet Nurse Corps program are only now beginning to reach graduation. Nevertheless the shortage of graduate nurses may prevail at least until 1949, since admissions to schools of nursing during this year have been lower than at any time in the past ten years. Only 30,899 student nurses were admitted in 1946, compared with 56,567 in 1945. Among the reasons cited are the competition of other occupations offering greater apparent satisfactions, the removal of wartime emotional and patriotic pressures, and the ending of Bolton act funds for nursing education.

The physician perhaps more than any other one person is likely to be consulted when a young woman thinks about entering the nursing profession. His aid is needed to encourage suitable candidates to enter an acceptable school of nursing. New drugs and new treatments often depend for their success on skilled nursing. A twenty-four hour span in a large hospital revealed, for instance, 58 surgical operations, 52 patients on the critical list, 12 babies born, 20 blood transfusions, 84 intravenous infusions, 141 streptomycin injections and 1,064 penicillin injections. The physicians who carry responsibility for these patients must have at their elbows professional nurses who act swiftly and intelligently.

Recent studies of the opinions of patients concerning nurses indicate that most people have high ideals of what the nurse should represent and feel more than normally injured and disappointed when she fails to measure up to them.

Employment conditions in nursing are gradually being improved as nurses, physicians and hospital administrators cooperate to secure better practices. Long hours and short pay were accepted as part of their lot by many nurses of an earlier generation. Offices, industries and public health nursing organizations which have been able to offer a more reasonable working day than some hospitals have accordingly attracted many nurses—some of them married or with domestic responsibilities—who might have preferred hospital service if the hours had been equally favorable. When hospitals have inaugurated a five day week of forty hours the shortage has become immediately lessened.

Many of the housekeeping and less skilled kinds of manual work which some nurses have done because of lack of other workers are gradually being assigned elsewhere. More practical nurses, well trained and state licensed, more orderlies, aides, ward maids and attendants are needed in the complex hospital world. Much of the distress about "nurse shortages" actually springs from a shortage of other types of personnel. The war demonstrated to physicians and nurses how much could be done, under supervision, by nurses' aides and other helpers. This is one of the conclusions formed from war experience that the medical profession will undoubtedly want to apply in civilian life. With its wider adoption, another block will be removed from the high school graduate's vision of professional nursing as a challenging occupation.

THE LABILITY OF BONE

The physical characteristics of bone are more obvious than its metabolic activity. The fact that bone is hard and rigid and appears so admirably to fulfil its mechanical functions is likely to turn attention from its capacity as a labile reservoir of mineral salts. Long before actual experimental demonstration the pathologist was aware of such abnormalities of mineralization or of decalcification as rickets, scurvy, osteitis fibrosa cystica and osteoporosis. More than a decade ago it was demonstrated[1] that restriction of experimental animals to a salt poor ration not only reduced the proportion of total bone ash but actually altered the chemical composition of the salt deposited in the growing skeleton. The mobilization of minerals from the skeleton is influenced by certain of the hormones. The thyroid hormones have been used in the removal of lead from the body after lead poisoning; the heavy metal appears to be mobilized from the bone along with the calcium phosphate with which it was deposited. Again, the hormone of the parathyroid glands has a definite effect on bone calcium; deficiency of this substance results in hypocalcemia and a resultant tetany, whereas an overproduction of the hormone produces hypercalcemia and net losses of calcium and phosphorus, which salts come from the skeleton. The estrogenic hormones bring about a pronounced shift of bone salts from the symphysis pubis[2] to the long bones in certain species,[3] with the result that the breaking strength of these leg bones is greatly increased[4] and the chemical composition of the bone salts is altered.[5] Purely physical evidence of the intense activity in the femur as a result of the administration of estrogens has recently been reported;[6] the x-ray diffractograms of sections of these bones show complete disorientation of bone salt crystals in the cortex. The same method of study has indicated that the faulty mineralization of the epiphysis in rickets is characterized by disorientation of the bone salt crystals[7] and that this abnormal structure persists after clinical healing is complete.[8] By means of a number of different chemical and physical experimental approaches it has been demonstrated that the skeleton is surprisingly labile: bone salts can be withdrawn from this reservoir under a variety of influences as well as deposited when circumstances are favorable. This fundamental concept has helped to explain certain clinical conditions and should be kept in mind in the therapeutic and nutritional approach to medical problems.

Current Comment

CANCER TREATMENTS FROM RUSSIA

The KR treatment,[1] named after its originators Nina Klyueva and Georgi Roskin, is now being tested in the treatment of human cancer in Moscow, Russia, by Trutnev, Lyampert and Egorov. The method is said to have little effect in cancer of the skin but to show promise in cancer of the throat, uterine cervix and breast. The preparation is made from dead protozoa of the species Trypanosoma cruzi. The material is said to localize in tumors and destroy them. This line of research followed the earlier observations of Roskin that living Trypanosoma cruzi after injection could destroy tumors in mice, although the animals themselves later succumbed to the infection. From the information at hand it is not possible to determine the biologic and chemical principles involved in the preparation and use of this material. Neither can its effectiveness be judged. In a second release[2] from the Russian Embassy brief mention of another method is said to be based on observations by Besredka. He found that a certain degree of immunity sometimes developed to transplanted tumors in animals when the transplants were made intracutaneously. Krasheninnikov used the method in 2 cases of human gastric cancer and 2 in which the type of primary tumor is not stated. He excised 1 to 2 Gm. of cancer tissue, wrapped it in a piece of omentum and transplanted it under the skin of the abdomen. It is stated that the transplant resolved promptly, as did also the primary tumor. It was believed that the transplanted cancer played the role of an autovaccine. The function of the omentum, presumably, was to supply cells for the fabrication of immune bodies. It will be, of course, some time before the value of this treatment can be judged. In order to answer satisfactorily questions in regard to these methods it is hoped that authoritative scientific information will soon become available.

FOCAL INFECTION

In his presidential address to the Institute of Medicine of Chicago Dr. Ernest E. Irons[1] discussed focal infection from the time when an Assyrian physician-priest in the seventh century told his king that the constitutional ailment from which he suffered was related to infected teeth to the revival of this doctrine by Frank Billings in the period from 1912 through 1916. Earlier investigators had arrived by empirical methods at the concept of a relationship between infection in the teeth and disturbances elsewhere in the body. With the coming of our modern era of bacteriology the infecting organism could be traced from its focus in the teeth or the throat or elsewhere in the body to tissues and organs far removed. Focal infection was no longer a theory but an established process. The difficulty of determining the exact nature of the relationship between a focus of infection and chronic arthritis is obviously far greater than prevails in tracing such an infection from a tooth to the heart or the kidney. Today the desirability of finding and removing local and often symptomless infection is generally recognized. However, the removal of great numbers of teeth or operations on the nose and throat on the chance of possible relationship between infection and chronic arthritis is no longer considered a scientific procedure. True, removal of chronic infections such as alveolar and peritonsillar abscesses may result in permanent cessation of arthritic attacks, but new technics in dental care and the development of specific chemotherapy and antibiotic therapy make available other approaches to the solution of this problem. In retrospect the intensive study carried on by Dr. Frank Billings and his associates, among them conspicuously Dr. Ernest Irons, produced not only observations of great importance in modern diagnosis and therapy but also concepts and procedures of significance in the control of other diseases. Among the chief of these by-products is the more careful examination of patients. Today the concept of focal infection has been integrated into the practice of medicine. One speaks no longer of the theory of focal infection; one recognizes focal infection as a definite pathologic condition requiring scientific diagnosis and treatment.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Jan. 6, 1947.

Need for Clarifying Lobbying Provisions of Reorganization Act

Provisions of the Reorganization Act may have to be amended by the 80th Congress to clarify the lobbying provisions. Already 205 individuals or organizations have registered, but many others have written to House and Senate officials to determine whether or not they should register. One lawyer suggested that a lobbyist should be defined as a person who approaches individual congressmen to enlist their support for or against pending bills. Parliamentary experts state that they did not believe that the lobbying provisions of the registration bill covered people whose only congressional activities involved testimony before committees, but they added that the provisions were not clear.

Penicillin Removed From All Distribution Control

The Civilian Production Administration has announced that penicillin has been freed from all distribution control. This action was taken because production is now adequate for all domestic and export requirements. Production reached 2.7 trillion Oxford units in October, compared with 675 billion units in October 1945 and 230 billion units in October 1944. Higher production was attributed to introduction of a new mold strain. The drug has been under some degree of control ever since 80 per cent of the meager initial output was first channeled to the armed forces in July 1943.

Army and Navy Merge Their Drive Against Vice

Although merger of the armed forces, which President Truman is expected to seek in the 80th Congress, still encounters opposition, the Army and Navy have joined hands in the "reduction and suppression of conditions inimical to the morals and welfare of service personnel." The objective of this merged activity will be to carry out the eight point program for the "repression of prostitution" in and around military establishments decided on last April.

Dr. James L. Hall to Resume Private Practice

Dr. James L. Hall, superintendent of Freedman's Hospital, has resigned to return to Chicago to resume private practice. Before coming to Washington in 1940 as professor of medicine at Howard University College of Medicine and chief of staff at Freedmen's, Dr. Hall had occupied positions on the staff of the Chicago Free Dispensary, Provident Hospital, Chicago, and as director of the Max Epstein Clinic.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 10-11. Dr. Victor Johnson, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Orthopedic Surgeons, Chicago, Jan. 25-30. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.

Central Surgical Association, Chicago, Feb. 20-22. Dr. Walter G. Maddock, 250 East Superior St., Chicago, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24-27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Southeastern Allergy Association, Atlanta, Ga., Jan. 18-19. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia 49, S. C., Secretary.

Council on Medical Service

SEAL OF ACCEPTANCE—COUNCIL ON MEDICAL SERVICE

At the last meeting of the members of the Council on Medical Service, the Council's Seal of Acceptance was granted to Louisiana Physicians Service, Inc., New Orleans; New Hampshire-Vermont Physicians Service, Concord, N. H., and the twenty-three member bureaus of the Washington State Medical Bureau. Final action on six additional applications was postponed. This brings to fifty-two the number of plans granted the right to use the seal.

Louisiana Physicians Service, Inc., is a statewide plan sponsored by the Louisiana State Medical Society with offices in the Tulane Building, New Orleans. Mr. Frank Lais Jr. is the executive director.

New Hampshire-Vermont Physicians Service is the result of the merging of New Hampshire Physicians Service, Concord, N. H., with Vermont Physicians Service, Rutland, Vt. The executive offices are located at Concord and the Executive Director is Mr. R. S. Spaulding. This is the first plan sponsored by the medical profession which covers the population of the two states under a single administrative office.

The twenty-three member bureaus of the Washington State Bureau are: Chelan County Medical Service Corporation, Wenatchee; Clallam County Medical Service, Corporation, Port Angeles; Clark County Medical Service Corporation, Vancouver; Columbia Medical Service Corporation, Pasco; Cowlitz County Medical Service Corporation, Longview; Grant County Medical Service Corporation, Coulee Dam; Grays Harbor County Medical Service Corporation, Aberdeen; Jefferson County Medical Service Corporation, Port Townsend; King County Medical Service Corporation, Seattle; Kitsap County Medical-Dental Business Bureau, Bremerton; Kittitas County Medical Service Corporation, Ellensburg; Lewis County Medical Service Corporation, Chehalis; Mason County Medical Service Corporation, Shelton; Okanogan County Medical Service Corporation, Okanogan; Pacific County Medical Service Corporation, Raymond; Pierce County Industrial Medical Bureau, Tacoma; Skagit County Medical Bureau, Mount Vernon; Snohomish County Physicians Corporation, Everett; Medical Service Corporation of Spokane County, Spokane; Thurston County Medical Service Corporation, Olympia; Walla Walla Valley Medical Service Corporation, Walla Walla; Physicians and Dentists, Inc., Bellingham, and Yakima Medical Service Association, Yakima.

The standards under which a plan is granted the Seal of Acceptance require that it must first have the approval of the state medical society or, if local, it must be approved by the local medical society in the area in which it operates. The members of the medical profession must assume responsibility for the medical services included in the benefits. The plan should have no regulation which restricts free choice of a qualified doctor of medicine who is practicing in the locality covered by the plan and who is willing to give service under the conditions established. The method of giving the service must retain the personal, confidential relationship between the patient and the physician. These and other qualifications must be met by plans seeking the right to use the Council's seal.

Of special interest regarding prepayment medical care plans on a nationwide basis is the fact that many firms with a large number of employees have expressed a desire to deal exclusively with plans which merit the Council's Seal of Acceptance.

GOVERNMENT SERVICES

VETERANS ADMINISTRATION

ADDITIONAL TRAINING UNDER THE VOCATIONAL REHABILITATION ACT

Some disabled veterans who need more than four years of training to reach their occupational objectives may be able to take additional training under the Vocational Rehabilitation Act. The Veterans Administration states that veterans so severely disabled that no course of training will restore them to employability in four years, and those who lose time in their courses because of their health or other personal circumstances beyond their control, are expected to be helped by this ruling. Provision also has been made for disabled veterans who started preprofessional courses before the war and who have since proved their suitability for their chosen profession but who still must have more than four years to prepare for it.

The ruling does not apply to any veterans in training under the G. I. bill whose eligibility is based on their length of service up to a maximum of forty-eight months of training. It will not affect the majority of disabled veterans enrolled under the Vocational Rehabilitation Act but only those in special circumstances.

Under this act the Veterans Administration is responsible for studying and testing the disabled veteran and helping him select an employment objective which is in line with his skill and suitable to his disability. The Veterans Administration then is responsible for planning and enrolling him in a course of rehabilitation training that will enable him to reach his objective and become employable, generally within the four year limit. VA pays tuition and fees, provides books and supplies and pays a subsistence allowance to give the disabled veteran a living income until he is employable again.

A disabled veteran who is found suited to a professional field such as medicine must have background and experience to show he had planned to go into that line and must have satisfactorily completed premedical courses before he became a veteran with sufficiently high grades to promise acceptance by a medical school. He must also show high promise of success in the field. If he meets these qualifications, the Veterans Administration may give him five years, or even more, of training under the Vocational Rehabilitation Act.

The way further has been left open for some veterans who cannot fill all those qualifications but want to keep their chosen objectives by taking part of their training at their own expense. If their background and experience indicate that they are qualified, the Veterans Administration may let them pay their own way long enough so that when they finally enroll under the Vocational Rehabilitation Act they have only four years or less to finish the course. VA warns, however, that the veteran who chooses this plan runs a danger, for if his physical condition changes materially while he is studying at his own expense he may no longer be in need of vocational rehabilitation when he wants it. Final decision for courses of more than four years rests with each VA regional manager acting on the written recommendation of a committee of his vocational rehabilitation, education and guidance specialists.

ENCEPHALOGRAPHY—TECHNICIANS NEEDED

The Veterans Administration has inaugurated a comprehensive program to train physicians and technicians in electroencephalography. The program is under the supervision of Dr. Frederic A. Gibbs of the University of Illinois. Training courses in this work up to two and one-half months, depending on previous experience, are being offered. Physicians interested in becoming associated with the Veterans Administration to train for this work may be detailed at once to the training course. This program is one of three nationwide programs now under way to implement existing specialists in the neuropsychiatry department. The other programs are in epilepsy and aphasia.

Technicians are given courses averaging six weeks at the Neuropsychiatric Institute of the University of Illinois, Chicago, and at the Veterans Administration Hospital, Hines, Ill. The courses for technicians are designed to equip them in the skill of using and maintaining standard instruments and to give them a basic understanding of encephalography. Basic salaries of technicians range from $2,168 to $2,394 a year, depending on experience. Dr. Paul R. Hawley, chief medical officer of the Veterans Administration, says that the positions for technicians are open to both men and women with or without experience.

Electroencephalography machines will be installed in all Veterans Administration hospitals of 1,000 beds or more and in the larger Veterans Administration mental hygiene clinics. Applicants for any of these positions should apply to the nearest Veterans Administration office.

ARMY OFFICERS LENT TO VETERANS ADMINISTRATION

The Army has taken constructive steps to give actual assistance to the veteran. In an address before the National Conference of Veterans Affairs, Washington, D. C., December 5, Secretary of War Robert P. Patterson said "To the Veterans Administration we have loaned as its chief one of our ablest officers, General Bradley, and we have made available other army officers to assist him. Today, in addition, there are more than eleven hundred army medical officers assigned to the Veterans Administration, as well as a small group of army doctors and nurses manning one Veterans Administration hospital until a VA staff can take over. So far we have turned over to the Veterans Administration twenty-four army hospitals, in most instances complete down to the last pair of slippers and dressing gown for the patients and to the last scalpel for the surgeon."

100,000 VETERANS' HOSPITAL BEDS

Authorized hospital capacity of the Veterans Administration has passed the 100,000 bed mark for the first time. The new record was set with the acquisition of six more army and navy hospitals in the program to provide beds for the increasing number of veterans who need hospitalization while VA's hospital construction project is in progress. The six recently acquired service hospitals are Cushing General, Framingham, Mass.; Fort Logan, Colo.; Billings General, Fort Harrison, Ind.; Newton D. Baker, Martinsburg, W. Va.; Moore General, Swannanoa, N. C., and the naval hospital at San Juan, Puerto Rico.

JEFFERSON BARRACKS HOSPITAL

Army engineers have awarded the architect-engineer contract for the Veterans Administration hospital at Jefferson Barracks, Missouri. The present hospital is a 597 bed general medical and surgical center, which, under the plans of the Veterans Administration, will be converted to a neuropsychiatric hospital and an additional 500 beds will be added.

PERSONAL

Dr. Charles W. Mayo of the Mayo Clinic, Rochester, Minn., has been appointed chairman of a special advisory group on the overall medical care for veterans. The group was appointed in compliance with public law 293, 79th Congress.

NAVY

RESERVE OFFICERS MAY RETURN TO ACTIVE DUTY

The Bureau of Medicine and Surgery has been authorized to recall to active duty, on a voluntary basis, reserve medical and dental officers now on inactive duty pending final action on applications for appointment to the Medical Corps of the regular Navy. Officers who volunteer will remain on active duty until such final action is taken on their applications. Under present regulations those officers are ineligible to apply for appointment to the regular Navy after the expiration of six months in an inactive duty status. By returning to active duty, reserve officers of the Medical and Dental Corps who have been in an inactive status beyond the six month limitation may regain their eligibility to file application for appointment to the regular Navy. Additional information on the procedure to be followed in applying for recall to duty may be obtained from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

TWO HUNDRED RESERVE NURSES NEEDED NOW

The Bureau of Medicine and Surgery announced the immediate need for the return to duty of 200 Naval Reserve nurses now on inactive duty. Volunteers, who will be required to serve for a minimum of one year, will be returned to active duty with the same rank as that held at the time they became inactive. As a result of demobilization the nursing staffs at naval hospitals have been sharply reduced while the number of patients has remained substantially the same during the past several months. The services of 200 additional nurses are considered necessary to meet the problem for the next year. All inactive members of the Naval Reserve Nurse Corps interested in returning to duty are urged to apply as soon as possible to the Superintendent of the Nurse Corps, Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

SIX PROMOTIONS TO REAR ADMIRAL

President Truman has approved the recommendations of the Navy selection board for the promotion of six medical corps officers to the rank of Rear Admiral. The medical officers recommended for promotion are: Morton D. Willcutts, Assistant Chief of the Bureau of Medicine and Surgery for Professional and Personnel Operations; Clarence J. Brown, Medical Officer in Command, Naval Hospital, St. Albans, N. Y.; Arthur H. Dearing, Medical Officer in Command, Naval Hospital, Oakland, Calif.; Paul M. Albright, Medical Officer in Command, Naval Hospital, Corona, Calif.; John C. Adams, Chief of Aviation Medicine Division, Bureau of Medicine and Surgery, and Carlton L. Andrus, Chief of Planning Division, Bureau of Medicine and Surgery.

NEW ORLEANS NAVAL HOSPITAL CLOSES

The U. S. Naval Hospital at New Orleans was disestablished as of November 15 on becoming surplus to the needs of the Bureau of Medicine and Surgery. It is said that consideration is being given to the transfer of this facility to the Veterans Administration.

PUBLIC HEALTH SERVICE

EXAMINATIONS FOR PUBLIC HEALTH SERVICE APPOINTMENTS

Examinations will be held early in 1947 for appointment to the Regular Corps of the United States Public Health Service. Seventy-five vacancies exist in grades of assistant and senior assistant scientist. Written examinations covering each candidate's particular field as well as related fields will be held April 14 and 15 at places mutually convenient to the applicant and the service. Oral examinations will be held February 13-April 9 in thirty cities throughout the United States.

Commissions are available to scientists trained in any of the following fields: bacteriology, mycology, parasitology, entomology, malacology, biology, chemistry, physiology, physics, statistics and psychologists and to milk and food specialists. Assignments will be in line with the individual's demonstrated ability and experience.

An applicant for the grade of assistant scientist must be a citizen of the United States, have had seven years of educational and professional training or experience, possess a certificate or diploma from an institution of recognized standing and be able to pass a physical examination given by a medical officer of the United States Public Health Service. The same requirements, plus an additional four years of training or experience, apply to those seeking the grade of senior assistant scientist.

Commissioned officers in the Regular Corps enjoy the same benefits and privileges as do officers of the Army, Navy or Marine Corps. The grade of assistant scientist is equal to that of first lieutenant in the Army. Annual pay, with allowance, for dependents, is $3,811. A senior assistant scientist ranks with a captain of the Army and draws, with allowances for dependents, $4,351 a year.

Public Health Service officers are entitled to full medical care and hospitalization for themselves and their families, including disability retirement at three-fourth's base pay. They receive thirty days' annual leave with pay. Periodic promotions are based on length of service and merit. The retirement age is 64.

Application forms may be obtained by writing the Surgeon General, Public Health Service, Washington 25, D. C.

MISCELLANEOUS

SALE OF SURPLUS SURGICAL SUTURES

Nationwide offerings of surplus surgical sutures on a sealed bid basis are being arranged by regions having large inventories, the War Assets Administration has announced. Various quantities of surgical sutures of all types, which were acquired by the government at a cost of about $3,500,000, will be offered to all buyers by War Assets Administration regional offices. Seven offices—Atlanta, Cincinnati, Denver, New York, Richmond, San Francisco and St. Louis—have been authorized to offer their entire inventories of sutures for sale at once. In addition, smaller quantities, which are stored in various other regions, will be combined to make up one or more additional offerings.

The surgical sutures are being segregated into three lots before being offered: (1) sutures made by Davis and Geck, Inc.; (2) those made by Johnson and Johnson, and (3) those made by all other manufacturers. Bids will be accepted on any one of the lots, any combination of lots or all three lots. Bids must be accompanied by a deposit of 10 per cent of the bid. Buyers must sign a contract to clear with the Food and Drug Administration before resale to assure that these sutures meet requirements of the Federal Food, Drug and Cosmetic Act.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

CALIFORNIA

Organize Graduate School of Medicine.—The College of Medical Evangelists, Loma Linda-Los Angeles, announces the organization of a graduate school of medicine giving courses on the graduate level and featuring the basic sciences as related to the major clinical specialties. The second course in the basic studies relating to surgery is now in progress. Nine month courses are also being offered in internal medicine and in obstetrics and gynecology. These basic science courses are planned primarily for physicians who are working toward certification by their respective American specialty boards.

Civil Service Examinations.—The California State Personnel Board has announced examinations for two state civil service positions. The examination for the first, chief, bureau of clinic diseases, will be February 1. Final date for filing application is January 30. The chief of the bureau, under administrative direction, plans, organizes, coordinates and directs the work of the staff of the bureau of chronic diseases in a program for prevention and control and for the study of public health aspects of chronic diseases, directs and interprets investigative projects, consults and advises provisional and local groups concerning programs for prevention of chronic diseases and addresses interested groups and prepares articles for publication. The salary range is from $535 to $655. The second position is that of senior public health analyst, with salary ranging from $280 to $340. The examination date is February 27 and the final date for filing application is February 6. The position does not call for a medical degree but for an education equivalent to graduation from college with courses in statistics. The senior public health analyst, under general direction, plans and supervises the work of junior public health analysts engaged in checking, tabulating, analyzing and interpreting morbidity and mortality data from public health records and in making other studies and health surveys. He assists in coordinating statistical activities and other procedures of the department of public health and also designs questionnaires. California residency is not required.

COLORADO

Personal.—Dr. Phineas J. Sparer, recently released from military service, has been named superintendent of the Sanatorium of the Jewish Consumptives Relief Society, Denver, which he has been serving as medical director.

Eastern Colorado Meeting.—At the regular meeting of the Eastern Colorado Medical Society in Burlington December 2, Dr. Edgar Durbin, Denver, gave a paper on "Shortcomings in Cardiac Diagnosis and Treatment"; Dr. Walter Kozak, Vandergrift, Pa., on "Urinalysis," and Dr. Harold M. Hayes, Burlington, on "Sedimentation Rate."

ILLINOIS

Record Birth Registration.—The Illinois Department of Health announced on December 20 a record breaking registration of live births in the third quarter of 1946 with 45,040 certificates filed. This number is 5,600 over the highest third quarter ever before recorded in Illinois. Births for the first nine months total 111,697 as compared with the 1945 figure of 98,204. Deaths associated with child bearing are at an all time low. Thus far a decrease of 15 per cent over the maternal death rate of 1945 has been recorded.

The Seventh Cancer Diagnostic Clinic.—The state director of public health, Dr. Roland R. Cross, has announced that a new state aided cancer diagnostic clinic was opened December 18 at the Marshall Browning Hospital of DuQuoin and that it was made possible through the cooperation of the Perry County Medical Society, the state department of health and the hospital authorities. This is the seventh to be established in the state, the others being in Chicago, Evanston, East St. Louis, Champaign, Rockford and Springfield. The purpose of these clinics is to provide expert assistance in the detection of cancer in its early stages. Each clinic is staffed by physicians qualified in the fields of surgery, internal medicine, x-ray and pathology.

Chicago

New Manager Takes Charge of World's Largest General Hospital.—Mr. Fred A. Hertwig on January 2 became warden of the Cook County Hospital, Chicago, succeeding Gen. Manus McCloskey. Among those present at the ceremony were William N. Erickson, president of the county board, and Dr. Karl A. Meyer, medical superintendent of county institutions. Mr. Hertwig, 48, previously was for many years manager of a hotel in Evanston.

Sanford R. Gifford Memorial Lecture.—The third annual Sanford R. Gifford Memorial Lecture will be presented under the auspices of the Chicago Ophthalmological Society on Monday, January 20, at the John B. Murphy Memorial Auditorium of the American College of Surgeons, 54 East Erie Street. Dr. Frederick C. Cordes, professor of ophthalmology, University of California Medical School, Berkeley-San Francisco, will present the lecture, which will be on "Types of Congenital Cataract."

Chicago Medical Society.—At the next meeting of the Chicago Medical Society, January 15, at the John B. Murphy Memorial Auditorium on East Erie Street, Dr. Willard M. Allen, professor of obstetrics and gynecology and head of the department, Washington University School of Medicine, St. Louis, will discuss "Functional Uterine Bleeding" and Dr. Laurence Randall, head of the section of obstetrics and gynecology, Mayo Clinic, Rochester, Minn., "Diagnosis and Treatment of Amenorrhea in Young Women."

Institute of Medicine.—Presentations by fellows of the Institute of Medicine of Chicago on recent contributions and current thought in the basic sciences and various branches of clinical medicine began January 10. Subsequent meetings will be held on the second and fourth Friday evenings of each month at the assembly room of the institute. They will be open without fee to all physicians and allied professional groups. Dr. Alvah L. Newcomb, associate in pediatrics, Northwestern University Medical School, and associate attending pediatrician, Children's Memorial Hospital, will open the series. His subject will be "Juvenile Diabetes."

INDIANA

Cancer Research.—Grants totaling $10,500 have been given to Indiana investigators by the American Cancer Society for projects in research on cancer, including among others two projects on mutations as they relate to cancer.

Personal.—Dr. Floyd T. Romberger, Lafayette, president of the Indiana Medical Society, addressed the sisters of St. Francis and the medical staff of St. Elizabeth Hospital, Lafayette, December 3.——Dr. Bert E. Ellis has been made president-elect of the Indianapolis Medical Society.——Dr. Charles E. Holland, Bloomington, has been appointed full time physician for the athletic team of Indiana University.

Countywide X-Ray Service.—The Lake County Tuberculosis Association and the James O. Parramore Hospital in connection with the Lake County Medical Society are conducting a countywide chest x-ray program. A new mobile x-ray unit has been purchased, and equipment will be installed in various communities in the county. Members of various groups in the county have been invited to appear for roentgenologic examination.

MISSOURI

Advisory Board to Los Alamos Project.—The Washington University School of Medicine, St. Louis, has concluded an agreement to advise on the health service and research carried on at the Los Alamos Project, Santa Fe, N. M., Charles Belknap, vice chancellor, Washington University, has announced. The medical advisory board consists of Dr. Philip Shaffer, distinguished service professor of biologic chemistry; Dr. Carl B. Moore, professor of internal medicine; Dr. Frank R. Bradley, director of Barnes Hospital; Dr. Otto Brandhorst, dean of the school of dentistry; Dr. Nathan Womack, associate professor of clinical surgery; Dr. James Nolan, assistant professor of obstetrics and gynecology, and Dr. Robert A. Moore, acting dean of the school of medicine. Dr. Norris Bradbury, Los Alamos Project director, and Col. Herbert Gee, commanding officer of the post, are ex officio members. The board will make recommendations for professional staff appointments on the medical service at Los Alamos. Other staff members of the school of medicine will be available for consultation to these groups. In return, some of the facilities of the Los Alamos Project will be available to qualified staff members of the school of medicine for research.

NEW YORK

Licenses Revoked.—The New York State Board of Medical Examiners has reported the following revocations of licenses, according to *Health News:*

Celano, Frank, 351 Madison Street, Westbury. Medical license issued through indorsement of his Maryland medical license and permitting him to practice medicine in the state of New York revoked, annulled and canceled as of Oct. 28, 1946.

Steuart, Frederick Charles, Sag Harbor, Long Island. Medical license to practice in the state of New York revoked, annulled and canceled as of Oct. 29, 1946.

Dr. Chant Goes to Johns Hopkins.—The board of health of Middletown recently gave a dinner to Dr. Harry L. Chant, state district health officer of Middletown, who is leaving the state service to become associate professor of public health at Johns Hopkins University, Baltimore. Dr. Chant graduated from the University of Buffalo School of Medicine in 1928, interned at St. Lukes Hospital Association, Jacksonville, Fla., and was resident physician at Buffalo City Hospital from 1929 to 1931.

Personal.—Dr. Jere J. McEvilly, Little Falls, has been appointed health officer of Little Falls to succeed Dr. Augustus B. Santry, who held the office for twenty-two years.——Dr. Charles A. Gordon, Brooklyn, has been appointed professor and head of the department of obstetrics and gynecology at the Long Island College of Medicine, Brooklyn, succeeding Dr. Alfred C. Beck, who retired after more than thirty years' service to the college.——Dr. Clark G. Rossman, Hudson, was guest of honor at a dinner, Sept. 25, 1946, given by the Columbia County Medical Society to mark his completion of fifty years in the practice of medicine.——Dr. John K. Miller, Albany, has been appointed associate director of the division of laboratories and research of the New York State Department of Health to succeed Dr. Mary B. Kirkbride, who retired July 1.——Dr. George Baehr was reelected president of the New York Academy of Medicine for a term of two years December 5.——Dr. James L. McCartney, Garden City, has been appointed consulting psychiatrist for the Great Neck Public Schools. Dr. McCartney, a veteran of the recent war, was for several years chief of the Division of Mental Hygiene of the State Department of Health, Connecticut.

New York City

Geriatrics Research Laboratory.—The city's first research laboratory devoted wholly to the study of geriatrics opened January 1 at the Brooklyn Hebrew Home and Hospital for Aged. It will be under the direction of the hospital's medical staff. The laboratories at the home and hospital were created by the Dora Brenner Research Fund.

New Society of Neurosurgery.—Twenty-four neurosurgeons who practice in the metropolitan area have recently formed the New York Society of Neurosurgeons. The organization is an outgrowth of a group of New York neurosurgeons who have been meeting informally at regular intervals since 1939. Dr. J. Lawrence Pool is president and Dr. Sidney W. Gross secretary.

Fourth Harvey Lecture.—Dr. Isaac Starr, professor of therapeutic research and dean of the medical faculty, University of Pennsylvania School of Medicine, will deliver the Fourth Harvey Lecture of the current series at the New York Academy of Medicine, New York, on January 16. Dr. Starr will speak on "The Ballistocardiograph: An Instrument for Clinical Research and Routine Clinical Diagnosis."

Anniversary of Health Department.—The eightieth anniversary of the foundation of the New York City Department of Health was celebrated at the Academy of Medicine, Nov. 6, 1946, when Dr. Israel Weinstein, city health commissioner, spoke on "Eighty Years of Public Health in New York City" and Dr. Harry S. Mustard, director, Columbia University School of Public Health, on the part which medical organizations and voluntary health agencies played in developing the activities of the health department.

Vaccination Required for All Dogs.—To stop the spread of rabies through the city the board of health decided early in December to require by law the vaccination of all dogs in the city. An amendment to the sanitary code would make it a misdemeanor to keep a dog unvaccinated against rabies, and violation of the amendment would be punishable by a $500 fine or imprisonment up to one year or both. Enforcement of the new amendment in the case of 300,000 licensed dogs in the city will be comparatively easy by merely requiring proof of vaccination to get a dog license. The spread of rabies has forced the board of health to put Queens, Brooklyn and Richmond under dog quarantine, and Health Commissioner Israel Weinstein believes that "it is only a question of time before infection will spread to Manhattan and the Bronx."

OHIO

Studies in Tropical Diseases.—The department of pharmacology, Western Reserve University School of Medicine, Cleveland, had received a grant of $16,500 from the United States Public Health Service to continue studies on tropical diseases begun during the war in that department.

Professor of Psychiatry Appointed.—Dr. Maurice Levine has been appointed professor and head of the department of psychiatry in the University of Cincinnati College of Medicine, according to Dr. Stanley Dorst, dean of the college. He will also be director of the psychiatry service of the Cincinnati General Hospital. Dr. Levine was an instructor in psychiatry at the Phipps Clinic, Johns Hopkins from 1929 to 1932 and a student of the Chicago Institute for Psychoanalysis from 1932 to 1936. He is a training analyst and a member of the faculty of the Chicago institute. He is also author of the book "Psychotherapy in Medical Practice."

PENNSYLVANIA

Establish Central Tuberculosis Register.—A chest x-ray survey of persons 15 years of age and over who live in Erie City and County reached the 80,000 figure Dec. 1, 1946. The survey is being participated in by the Erie County Health and Tuberculosis Association, the state department of health, the county medical society and official, voluntary, business and welfare organizations. At the annual dinner meeting of the Erie County Health and Tuberculosis Association, November 12, Dr. Edward Chamberlain, professor of radiology and roentgenology, Temple University School of Medicine, Philadelphia, emphasized the importance of thorough follow-up of findings coming out of the survey. Other features of the county's vigorous program include the establishment of a central tuberculosis case register, employment of a Negro health education worker, placing x-ray units in the two general hospitals in Erie and considerable improvement in the health education program.

VIRGINIA

Dr. Newbill Named Superintendent of Sanatorium.—Dr. Hugh Page Newbill took charge of DeJarnette Sanatorium, Staunton, January 1, succeeding Dr. J. S. DeJarnette, resigned. Dr. Newbill was assistant professor of neurology and psychiatry at the University of Virginia School of Medicine and was associated with the Davis Clinic of the University of Virginia Hospital at the time of his appointment.

Changes in Health Officers.—The State Department of Health of Virginia announced the appointment of Drs. J. C. Neale Jr., Norfolk, formerly assistant director of local health services, appointed director of local health services as of Nov. 1, 1946; Peyton M. Chichester, Abingdon, formerly assistant director of local health services, appointed acting director of the bureau of crippled children and tuberculosis outpatient service as of November 1; Jack B. Porterfield, Richmond, appointed assistant director of local health services as of November 1, and William A. Browne, Richmond, appointed director of communicable disease control as of December 1.

WEST VIRGINIA

Personal.—Dr. Norman L. Cardey, formerly of Winona, who served in the Army Medical Corps for over five years and was released from service in September 1946, is now serving a residency in surgery at the California Hospital in Los Angeles.

Diet Cards Available.—Nutritional feeding cards are being distributed by the state health department and the state nutrition committee for the use of physicians interested in infant and child feeding. The form adopted was recommended by a committee appointed by the state nutrition committee at a meeting early last year. According to Miss M. E. Ingoldsby, president of the state nutrition committee, the cards are being printed and distributed to meet the demand of physicians who desire to give them to their patients.

Cancer Research Funds Allotted.—West Virginia will receive between $20,000 and $30,000 for cancer control activities from a special appropriation of $2,500,000 now being distributed by the U. S. Public Health Service. The appropriation made during the closing days of the last session of

Congress is being allocated to the various states on the basis of population and need. The amount of federal funds received by West Virginia will augment the state appropriation of $50,000 for the division of cancer control of the state health department. It will be used for furtherance of the educational program and aid in the establishment of tumor clinics and tissue diagnostic service for needy cancer patients and for the care of needy cancer patients if the prognosis is good. Federal funds will not be used for palliation or for terminal care of advanced cancer patients. The receipt of federal funds has provided for the expansion of the overall cancer program in this state. It has enabled the division of cancer control to authorize limited diagnostic studies in suspected cancer patients and increase active treatment for needy patients.

CANAL ZONE

Canal Zone Medical Society.—At the December meeting of the Medical Association of the Isthmian Canal Zone the following program was presented: Dr. Jesse C. Ellington, Ancon, "Revaccination as an Index of Immunity to Smallpox," and Dr. J. E. Elmendorf, New York, "A Preliminary Report on Field Experiments to Demonstrate Effectiveness of Various Methods of Malaria Control" (with slides).

GENERAL

Conference on Epilepsy.—The Association for Research in Nervous and Mental Disease joined the International League Against Epilepsy for the twenty-sixth annual meeting December 13 at the Hotel Waldorf-Astoria, New York. The subject of the conference was epilepsy. Dr. William G. Lennox, Boston, was chairman of the program committee.

Campaign for Funds to Fight Poliomyelitis.—The annual "March of Dimes" campaign conducted by the National Foundation For Infantile Paralysis to raise funds to continue the fight against epidemic poliomyelitis will be conducted throughout the country January 15-30. More than 1,000 radio stations will participate in the campaign, and various other means of bringing to the public the importance of this work have been organized.

American Academy of Allergy.—At the meeting of the American Academy of Allergy held in New York City November 25 to 27 the following officers were elected for the ensuing year: Dr. Will Cook Spain, New York, president; Dr. Karl D. Figley, Toledo, Ohio, vice president; Dr. Theodore L. Squier, Milwaukee, secretary, and Dr. Leo H. Criep, Pittsburgh, treasurer. One hundred and forty-four new members were elected. The academy at present consists of one hundred and seventy-one fellows and three hundred and forty-one members. The next meeting will be held in St. Louis December 15 to 17.

American Society of Electroencephalography.—The Eastern Association of Electroencephalographers last June requested representatives of the American Physiological Society, American Neurological Association, American Psychiatric Association and American Medical Association to form a council of seven members for the purpose of organizing the American Society of Electroencephalography. The council met in December 1946 in Boston and formed the American Society of Electroencephalography, with Herbert H. Jasper, Sc.D., Montreal, Canada, president; Dr. Frederick A. Gibbs, Chicago, vice president, and Dr. Robert S. Schwab, Boston, secretary.

Diabetes Association Aids Research.—An invitation to apply for funds to aid research in clinical and experimental diabetes is extended to medical graduates and workers in allied fields by the New York Diabetes Association. An application for the grant should contain a description of the project and the name of the laboratory or individual under whose guidance the work will be done and should have the approval of the head of the department in which the work is to be done. Applications should be filed on or before February 15 with Dr. Edward Tolstoi, chairman, Committee on Research, New York Diabetes Association, Inc., 2 East 103d Street, New York 29.

Frank Calderone Heads Commission of World Health Organization.—The Interim Commission of the World Health Organization, a special agency of the United Nations, has announced the appointment of Dr. Frank A. Calderone as director of its headquarters office being established in the Empire State Building, New York City. Dr. Calderone is a graduate of New York University College of Medicine, where he also taught pharmacology and preventive medicine. He received a degree in public health from the School of Hygiene, Johns Hopkins University, is a member of the New York County Medical Society, the Harvey Society, Alpha Omega Alpha and the American Public Health Association. He was with the New York City Health Department for ten years.

Meeting of Parasitologists.—The twenty-first annual meeting of the American Society of Parasitologists was held Dec. 26 to 28, 1946 at Harvard Medical School and also at the Statler Hotel, Boston. Among numerous papers read at the meeting were the following: The Occurrence of Small Strains of Endameba Histolytica in the Chicago Area; Studies on the Life Cycle and Viability of Leishmania Tropica; A Symposium on Trichomonas, and Methods of Testing Fabrics and Ointments to Determine Their Effectiveness as Barriers to Schistosome Cercariae. One afternoon was devoted to demonstrations and motion pictures on Sandfly Control and Schistosomiasis. The presidential address, entitled "This Wormy World," was delivered by Norman L. Stoll of the Rockefeller Institute for Medical Research, Princeton, N. J.

American Foundation for High Blood Pressure.—Creation of the American Foundation for High Blood Pressure to support and develop research in the field of high blood pressure and arteriosclerosis has been announced by Alva Bradley, chairman. Donald E. Hagaman, Cleveland, will take office in February as executive secretary. The board of scientific directors has been drawn from specialists in cardiovascular disease from the entire country. Funds raised on a national scale to finance research in the cause and cure of high blood pressure in American medical colleges, medical centers and hospitals is the objective of the foundation. Cost of the administration of the program has already been financed on a three year basis. While high blood pressure and arteriosclerosis account for a fourth of the deaths above the age of 40, funds for research have ranked at the bottom of the list among those available for research into major causes of incapacity and death, Mr. Bradley said.

Psychiatric Personnel Placement Service.—The activities of the Psychiatric Personnel Placement Service, jointly operated for the past year as an emergency placement program by the American Psychiatric Association and the National Committee for Mental Hygiene, have been taken over by the latter organization, 1790 Broadway, New York 19. Physicians seeking placement in positions or training in the field of psychiatry may still apply. Over nine hundred physicians have registered in the placement service since it began operating Dec. 11, 1945 for the purpose of giving advice and assistance to physicians in the armed forces who were interested in obtaining further training or to physicians in psychiatry on their return to civilian life. It is felt, however, that the emergency placement program has been completed but that the data relative to training and positions should be kept available to interested physicians. Complete files will be located in the offices of the National Committee for Mental Hygiene.

Southern Medical Association.—At the recent meeting of the Southern Medical Association in Miami, Fla., the following officers were elected: Dr. Lucien A. LeDoux, New Orleans, president, and Drs. Oscar B. Hunter, Washington, D. C., and Robert T. Spicer, Miami, vice presidents. The Association's medal for scientific research was presented to Dr. William H. Sebrell Jr., chief, Division of Physiology, National Institute of Health, Bethesda, Md., for his contributions to the study of nutrition and its effect on public health. Among the awards for scientific exhibits, the first one was made to Drs. Amos Christie and J. Cyril Peterson of Vanderbilt University School of Medicine, Nashville, Tenn., for their exhibit on pulmonary calcifications and histoplasmin sensitivity. The second award went to Dr. J. Brown Farrior, Tulane University School of Medicine, New Orleans, for his exhibit on ear surgery, and the third to Dr. Keith S. Grimson, Dr. George J. Baylin, Haywood M. Taylor, Ph.D., Dr. Frederick H. Hesser, Dr. Ralph W. Rundles and Dr. Robert C. Smith of Duke University School of Medicine, Durham, N. C., for their exhibit on vagotomy for peptic ulcer.

Paul Russell Awarded Walter Reed Medal.—The American Society of Tropical Medicine has awarded the Walter Reed Medal for 1946 for meritorious achievement in tropical medicine to Dr. Paul F. Russell of the International Health Division of the Rockefeller Foundation, now assigned to service in Venezuela. Dr. Russell was born in Boston, graduated from Cornell University Medical School in 1921 and received the degree of master of public health at Harvard in 1929. His first significant contribution to the field of malariology concerned "species control" in antimalaria campaigns. His studies on the transmission and epidemiology of malaria in the Philippines and his encouragement of the development of totaquine laid the foundation for an intelligent approach to the problem of malaria control. His studies in India on transmission clarified the epidemiology of malaria. At the beginning of World War II Dr. Russell returned to the United States, was commissioned a lieutenant colonel and was assigned to the Surgeon General's Office, where he conceived the idea of forming malaria survey units and malaria control units, the organization and training of which he planned, later going to Algiers as director of the Allied School of Malaria and chief malariologist of the Allied forces in the North African Theater. He returned to the United States in 1944 and became chief of the Division of Parasitology at the Army Medical School, Washington, D. C., until his return to civilian life early in 1946. Dr. Russell's bibliography consists of more than 120 scientific papers.

Grants for Research in Endocrinology.—The committee on research in endocrinology, National Research Council, announces that requests for grants-in-aid during the fiscal year July 1, 1947 to June 30, 1948 will be received until Feb. 28, 1947. Application blanks may be obtained by addressing the secretary, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D. C. In addition to a statement of the problems and research plan or program, the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient institution for administrative expenses. The committee makes grants-in-aid of research in the general field of experimental and clinical endocrinology. However, applications for support of research in the problems of sex in the narrower sense cannot be given favorable consideration, and investigators seeking support in this field should direct their proposals to the committee for research in problems of sex of the National Research Council. The committee on research in endocrinology, however, will continue to give consideration to the support of studies of the effect of sex hormones on nonsexual functions, e. g., on general metabolism and on the metabolism of steroid hormones.

LATIN AMERICA

Congress of Pharmacology.—The third Pan American Congress of Ophthalmology will be held in Havana, Cuba, Feb. 23-28, 1948, under the presidency of Dr. Tomas R. Yanes (THE JOURNAL, October 5, p. 299).

New Medical Society.—The Sociedad Ycateca de Obstetricia y Ginecologia with headquarters at Calle 59, Numero 539, Merida, Yucatan, Mexico, was recently established with Drs. Eduardo Urzaiz Rodriguéz president, Fernando Narvaez Aguilar vice president and Manual Espinosa Sierra secretary.

New Journal.—The *Revista de Nutricion,* the organ of the Instituto Nacional de Nutricion of Lima, Peru, recently appeared. The headquarters of the *Revista* is at Ave. Salaverry, Lima, Peru. The first issue does not indicate how often it will be published.

First Inter-American Congress on Brucellosis. — Bi-yearly conferences on brucellosis have been in progress in Mexico since 1930. The fourth was held in Morelia, Mexico, July 1944. The fifth congress was held in Mexico City Oct. 28-Nov. 2, 1946 under the sponsorship of Dr. Jose Zozaya, chairman of the National Brucellosis Commission; the Mexican Society of Tropical Medicine, of which Dr. S. Gonzales Herrejon is chairman, and the Organization Committee of the Congress for the Study of Brucellosis, of which Dr. M. Ruiz Castañeda is chairman. This meeting became the first Inter-American Congress on Brucellosis and was attended by invited speakers from Argentina, Brazil, Cuba, El Salvador, Bolivia, Colombia and Puerto Rico. From the United States were Alice C. Evans, senior bacteriologist of the United States Public Health Service (retired); I. Forest Huddleson, research professor in bacteriology, Michigan Agricultural Experiment Station, Michigan State College; C. F. Jordan, epidemiologist, Iowa State Department of Health; V. T. Schuhardt, University of Texas, Galveston; Joseph D'Antoni, Tulane University, New Orleans; H. J. Schmidt, Mississippi (formerly Tulane University); James P. Campbell, Wheaton, Ill.; Mayor J. Moss, Muncie, Ind.; H. M. Powell, Indianapolis, and Harold J. Harris, New York. The opening address was given by Harris, who reviewed the milestones in the study of brucellosis from the time of Bruce and stressed the contributions made by researchers and clinicians in this hemisphere. Evans discussed public health aspects of brucellosis, Huddleson the unsatisfactory status of cattle vaccination and the possibilities of an improved method, Schmidt the changing virulence of Brucella abortus and its tendency to become a chronic infection, D'Antoni intestinal brucellosis, Schuhardt the chemotherapy of brucella infection in cattle, Campbell the possibility of human transmission, Harris technical factors, uses and limitations of the opsonocytophagic test, and Jordan the epidemiology of brucella infection. (The paper by Harris was prepared with the collaboration of Blanche L. Stevenson, R.N., and Jacoba V. Schochat, B.A.). Important papers from the Spanish speaking countries were presented by Emmanuel Dias, Brazil; Francisco De La Cruz, Cuba; M. Ruiz Castañeda, Mexico; Elidberto Fernandez Ithurrat, Buenos Aires; the late Salvador Mazza, Buenos Aires; Andres Soriano, Bogota, Colombia; Felix Veintemicla, La Paz, Bolivia; Petro Menendez and Roberto Vargas, El Salvador; Oulton Carlos, Cordoba, Argentina; A. Pomales-Lebron, San Juan, Puerto Rico; T. Villefana Lastra, Cordoba, Argentina; C. Carrillo Cardenas, Mexico; Sabino Di Rienzo, Cordoba, and E. Criscuolo, Cordoba, among others. Other papers covering virtually the entire field of brucellosis from the clinical and laboratory points of view were presented. The increasing recognition of the disease in various Central and South American countries became apparent from the data presented. The majority of infections were reported to be of the melitensis (goat) variety. Of interest was the fact that ingestion of cheese made from raw milk of goats and cows accounted for the largest percentage of cases in Mexico City, milk being boiled before used as such. Dr. Alice C. Evans was elected president. An inter-American Committee on Brucellosis was appointed consisting of Alice C. Evans of the United States, chairman; Dr. M. Ruiz Castañeda, Mexico; Dr. Salvador Mazza, Argentina, and Dr. I. F. Huddleson, East Lansing, Mich. This committee was empowered to bring to the attention of the proper division of the United Nations the importance of forming a world organization to deal with the problem of brucella infection in animals and man. The second Inter-American Congress on Brucellosis is to be held in Argentina in 1948, probably in April.

FOREIGN

Gift of Radium to Switzerland.—Belgium has offered 3 Gm. of radium to Switzerland in gratitude for "hospitality granted Belgian refugees during the war," the Swiss radio announced. In accepting the gift, the Swiss government said that it would be used in the fight against cancer.

Course of Urology.—A course of urologic instruction will be presented at St. Peter's and St. Paul's hospitals, London, beginning in January and continuing throughout April. A six months' course will begin on the conclusion of the postgraduate course. The fee for the three months' course is 15 guineas payable in advance. Applications should be made to the secretary, St. Peter's Hospital for Stone, Henrietta Street, London, W. C. 2, England.

Congress on School Hygiene.—The French Society for School Hygiene and the Society of Medical Inspectors of the Schools in the Seine district are sponsoring a Congress on School and University Hygiene in Paris, June 25 to 29, 1947 under the auspices of the ministers of education and public health. Physicians interested in school hygiene in various countries are invited to participate either as discussants or as reporters. Participation and registration are free. At that time the French Society for School Hygiene will propose the creation of a commission to be charged with the organization of periodic congresses concerning school hygiene.

Marriages

JAMES MARSHALL SKINNER JR., New Martinsville, W. Va., to Miss Mary Elizabeth Hurban of Powhatan Point, Ohio, June 6.

HAROLD HENSTORF, Farragut, Iowa, to Miss Marie D. Richter of St. Cloud, Minn., in Kansas City, Kan., August 8.

JOHN WILLIAM VANDERBILT, Plattsburgh, N. Y., to Miss Marguerite Jean Orr of Ormstown, Quebec, Canada, August 14.

JACK H. NEESE, Charlotte, N. C., to Miss Jacquelyn Reflogal of Clearwater, Fla., in Monroe, N. C., August 9.

HAROLD IRA HARVEY, New Britain, Conn., to Miss Ada Patricia Hawe of Binghamton, N. Y., June 20.

ALBERT HAROLD WILLIAMS, Revere, Mass., to Miss Loise Carol Schear of Evansville, Ind., September 8.

GABRIEL P. JOSEPH, Myrtle Beach, S. C., to Miss Mary Elizabeth McAlhany of Branchville, August 5.

LESLIE STALBLER PIERCE to Miss Mary McNair Cadzow, both of Greensburg, Pa., September 14.

MORTON NATHANSON, New York, to Miss Peggy Lee Prag of Richmond, Va., September 1.

CHARLES F. SHERWIN, St. Louis, to Miss Myra Murrell of Lonedell, Mo., August 11.

Deaths

Paul Pressly McCain ⊕ Sanatorium, N. C.; born in Due West, S. C., June 26, 1884; University of Maryland School of Medicine, Baltimore, 1911; assistant professor of medicine at the Duke University School of Medicine in Durham; specialist certified by the American Board of Internal Medicine; awarded the Moore County Medical Society medal for his paper presented at the 1928 annual session of the Medical Society of the State of North Carolina, of which he had been president; past president of the Buncombe County Medical Society; served as president, vice president, member of the board of directors and executive committee of the National Tuberculosis Association; past president of the Southern Tuberculosis Conference; director and member of the executive committee of the North Carolina Tuberculosis Association; member of the American Trudeau Society, serving as a member of its council from 1939 to 1942, American Clinical and Climatological Association and the Southern Medical Association; member of the subcommittee on tuberculosis of the National Research Council; since 1924 superintendent, medical director and director of the extension department of the North Carolina Sanatorium for the Treatment of Tuberculosis, where he was chief of medical service and assistant superintendent from 1914 to 1923; served as superintendent of the Western North Carolina Sanatorium in Black Mountain and the Eastern North Carolina Sanatorium in Wilson; received an honorary LL.D. degree from the University of North Carolina in 1936; on the editorial board of the *North Carolina Medical Journal;* trustee of the Flora Macdonald College, Red Springs; killed instantly near Raleigh Nov. 25, 1946, aged 62, when his automobile collided with a bus while he was on his way to attend a medical meeting.

Eugene Anthony Stack, Chicago; born in Chicago, March 28, 1908; Loyola University School of Medicine, Chicago, 1935; interned at the Cook County Hospital and the Kankakee (Ill.) State Hospital; served a residency at the Municipal Contagious Disease Hospital, Presbyterian Hospital and the Children's Memorial Hospital; member of the American Medical Association; specialist certified by the American Board of Pediatrics; began active duty as a lieutenant in the medical corps of the U. S. Naval Reserve in March 1943 and released from active duty with the rank of lieutenant commander in February 1946; on the staffs of St. Anne's and Children's Memorial hospitals; died in the Belmont Hospital Dec. 1, 1946, aged 38, of a skull fracture received in an automobile accident.

Ira Clyde Miller ⊕ Harrisburg, Pa.; born in Johnstown, Pa., March 22, 1895; University of Pittsburgh School of Medicine, 1928; special epidemiologist of the Pennsylvania Department of Health; also a graduate in pharmacy; interned at St. Francis Hospital in Pittsburgh; served in France during World War I; began active duty in the medical corps, Army of the United States, in June 1941; spent eighteen months as the commanding officer of the 12th Hospital Center in England; awards include the Bronze Star; service terminated in May 1946 with the rank of colonel; died Oct. 31, 1946, aged 51, of carcinoma of the parotid gland.

William Leland Holt, Amherst, Mass.; Harvard Medical School, Boston, 1905; member of the American Medical Association; formerly college physician at the Massachusetts State College; served as health officer of Hot Springs National Park, Ark., as professor of hygiene and university physician at the University of Tennessee at Knoxville and as director of the division of communicable diseases and social hygiene in the state department of health of Maine; died in the Cooley Dickinson Hospital, Northampton, Oct. 18, 1946, aged 67, of shock following a prostatectomy.

Julius Ord Arnson ⊕ Bismarck, N. D.; Northwestern University Medical School, Chicago, 1911; specialist certified by the American Board of Internal Medicine; fellow and governor of the American College of Physicians; interned at St. Barnabas Hospital in Minneapolis; served in France during World War I; member of the board of editors of the *Journal-Lancet;* part owner of the Quain and Ramstad Clinic; on the staffs of St. Alexius Hospital and the Bismarck Evangelical Hospital, where he died Oct. 29, 1946, aged 58, of coronary thrombosis.

William Edward Patterson ⊕ Minneapolis; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; served as assistant professor of ophthalmology at the University of Minnesota Medical School and the graduate school; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; formerly vice president of the Hennepin County Medical Society; on the staffs of Asbury and St. Barnabas hospitals; died Oct. 30, 1946, aged 71, of pulmonary embolism.

John Ashworth, Chicago; born in Chicago, Dec. 16, 1906; Northwestern University Medical School, Chicago, 1935; member of the American Medical Association; interned at the Cook County Hospital, where he engaged in research work; instructor in the department of medicine at his alma mater; began active duty as a major in the medical corps, Army of the United States, in July 1942; released from active duty June 25, 1946 with the rank of lieutenant colonel; died in the Belmont Hospital Dec. 2, 1946, aged 39, of injuries received in an automobile accident.

Frederick Beekel, East Cleveland; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906; member of the Cleveland Academy of Medicine and the Cleveland Medical Library; for many years on the staff of the Cleveland City Hospital; died Nov. 3, 1946, aged 65, of coronary heart disease.

Harry Granville Bonnell, Tucson, Ariz.; Starling Medical College, Columbus, Ohio, 1900; member of the American Medical Association; died recently, aged 72.

Lynn Brownell Chase ⊕ Morrisville, N. Y.; University of the City of New York Medical Department, New York, 1893; past president of the Madison County Medical Society; director and vice president of the First National Bank of Morrisville; first president of the board of education of the Morrisville Central School district; served as school physician, health officer of the town of Eaton and village of Morrisville; director of the Business Men's Association; died Nov. 3, 1946, aged 73, of heart disease.

John Summerfield Cherrington ⊕ Logan, Ohio; Ohio Medical University, Columbus, 1897; for many years co-owner and chief of the surgical staff of the Cherrington Hospital; died in the Hocking Valley Hospital Oct. 22, 1946, aged 74, of cerebral embolism.

Mayer S. Coffler ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1913; served during World War I; died in the Mount Sinai Hospital Oct. 16, 1946, aged 59, of hypernephroma of the left kidney.

Percival F. Dalphin. ⊕ Malone, N. Y.; Bellevue Hospital Medical College, New York, 1891; served during the Spanish-American War and World War I; formerly associated with the U. S. Public Health Service; on the staff of the Alice Hyde Memorial Hospital; died Sept. 24, 1946, aged 78, of chronic interstitial nephritis and hypertrophied prostate.

David A. Dickson, Grand Rapids, Mich.; Detroit College of Medicine, 1904; also a graduate in pharmacy; on the staff of the Butterworth Hospital, where he died Oct. 31, 1946, aged 75, of pulmonary tuberculosis.

Esgar Bowen Foltz ⊕ Akron, Ohio; Medical College of Ohio, Cincinnati, 1899; trustee of the Akron Art Institute and the Summit County Historical Society; for many years jail physician; died in the People's Hospital Oct. 22, 1946, aged 73, of arteriosclerosis, asthma and anemia.

Grant W. Gregg, Ashland, Ore.; Medical College of Ohio, Cincinnati, 1890; on the staff of the Community Hospital; member of the school board and city councilman; died Oct. 9, 1946, aged 81, of coronary thrombosis.

Henry M. Haynes, Gatesville, Texas; Dallas Medical College, 1904; member of the American Medical Association; past president of the Coryell County Medical Society; for many years city health officer; died recently, aged 70, of coronary thrombosis.

William Brown Heagerty, Sierra Madre, Calif.; L.R.C.P., L.R.C.S., Edinburgh, and L.F.P.S., Glasgow, Scotland, 1900; formerly associated with the Indian Service; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; died recently, aged 70.

Ira Dorman Nelson, Albuquerque, N. M.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904; for many years associated with the Indian Service, serving as superintendent of many of its hospitals; died Oct. 6, 1946, aged 68, of carcinoma.

William Oscar Pollard, Speers Ferry, Va.; Medical College of Virginia, Richmond, 1904; member of the American Medical Association; died Oct. 28, 1946, aged 68, of injuries received in an automobile accident.

R. Ford Ratliff, Lucedale, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1901; member of the American Medical Association; died Oct. 16, 1946, aged 68, of cardiorenal disease.

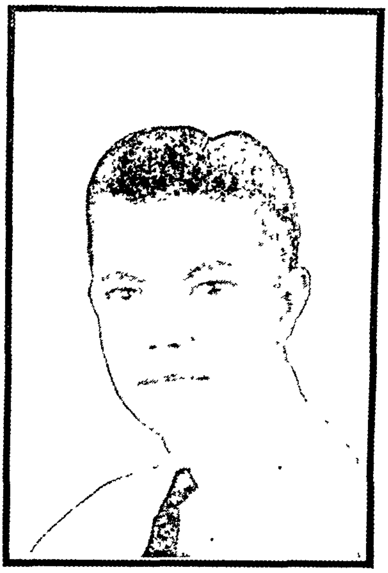
Claudius J. Riddick, Suffolk, Va.; Bellevue Hospital Medical College, New York, 1890; member of the American Medical Association; served as county physician; on the staff of the Virginia General Hospital; died Oct. 18, 1946, aged 87, of arteriosclerosis.

Frederick Arthur Rieckhoff, Ridgeville Corners, Ohio; Ohio State University College of Medicine, Columbus, 1917; member of the American Medical Association; died in Minneapolis Oct. 29, 1946, aged 55, of heart disease while en route from Chicago to Minneapolis on a plane.

Harry Rubinstein ⊕ Pittston, Pa.; Medico-Chirurgical College of Philadelphia, 1910; served during World War I; connected with Pittston Hospital; died Oct. 13, 1946, aged 65, of acute cardiac dilatation.

John Joseph Sheehey ⊕ Graymoor, N. Y.; University of Wooster Medical Department, Cleveland, 1891; Affiliate Fellow of the American Medical Association; served on the staffs of the Coney Island, Samaritan, Harbor and Caledonia hospitals in Brooklyn; retired to the Franciscan Monastery to serve as physician for the Friars; died in St. Clare's Hospital in New York Oct. 2, 1946, aged 79, of myocardial failure.

Lieut. Felix B. Long Jr. (MC), U. S. Navy, 1915-1942



Lieut. Louis W. Streuter (MC), U.S.N.R., 1914-1945

Oscar Henry Shepard, O'Donnell, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1905; died in a hospital at Lubbock recently, aged 75, of coronary thrombosis.

David Herman Smith, Millbrook, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1894; served on the staffs of Mercer (Pa.) Cottage and Grove City (Pa.) hospitals; died Oct. 21, 1946, aged 78, of arteriosclerosis.

William S. Stanley, Milwaukee; Milwaukee Medical College, 1900; member of the American Medical Association; died Oct. 27, 1946, aged 69, of hypertensive heart disease.

Edward Clayton Stroud, Marietta, S. C.; University of the South Medical Department, Sewanee, Tenn., 1899; honorary member of the South Carolina Medical Association and the Greenville County Medical Society; died Oct. 2, 1946, aged 71.

Mathias Sundt ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; on the staff of the Fairview Hospital, where he died Oct. 21, 1946, aged 63, of carcinoma of the colon.

Robert Edward Timberlake ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1914; for many years physician for the city health department; died in the Stuart Circle Hospital Oct. 27, 1946, aged 56, of a ruptured diverticulum.

Edward Patrick Troy, Chicago; Northwestern University Medical School, Chicago, 1914; member of the American Medical Association; interned at Cook County Hospital in 1916, when he joined the City of Chicago Municipal Tuberculosis Sanitarium, where he was superintendent of dispensary service for many years; at one time physician in charge of the Robey Street Dispensary; served during World War I; died Dec. 11, 1946, aged 59, of cerebral hemorrhage.

James Frederic Wagner, Bristol, Pa.; Jefferson Medical College of Philadelphia, 1904; member of the American Medical Association; served as a member and president of the Bristol borough council and board of health; past president of the Bucks County Medical Society; fellow of the American College of Surgeons; died in Southington, Conn., Oct. 7, 1946, aged 67, of cerebral thrombosis.

Otto Wagner ⊕ Elizabeth, N. J.; Cornell University Medical College, New York, 1903; member of the Board of Fire Commissioners and director of Elizabeth Trust Company; formerly city physician and member of the city council; consulting physician at Alexian Brothers Hospital, St. Elizabeth Hospital and Elizabeth General Hospital, where he died Oct. 22, 1946, aged 74, of carcinoma of the rectum.

Wilber Lloyd Warren ⊕ Gilman City, Mo.; John A. Creighton Medical College, Omaha, 1916; served as a member of the Selective Service Board; on the staff of the Wright Memorial Hospital in Trenton; died Oct. 29, 1946, aged 57, of cardiac decompensation.

Louis Weber, West Baden, Ind.; University of Louisville Medical Department, 1898; for many years assistant medical director for the Commonwealth Life Insurance Company in Louisville; died in St. Joseph Infirmary, Louisville, Oct. 25, 1946, aged 71, of cerebral hemorrhage.

Jabez William West, Idaho Falls, Idaho; Western Reserve University School of Medicine, Cleveland, 1918; member of the American Medical Association; died suddenly Oct. 11, 1946, aged 61, of coronary thrombosis.

George David Wilde ⊕ Fort Edward, N. Y.; Albany Medical College, 1904; in 1922 became associated with the medical department of Endicott-Johnston Corporation; died recently, aged 66, of hypertensive heart disease and coronary thrombosis.

KILLED IN ACTION

Felix Benjamin Long Jr., Assistant Surgeon, Lieutenant, U. S. Navy, Starkville, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1940; interned at the Southern Baptist Hospital in New Orleans; entered the medical corps of the U. S. Naval Reserve as a lieutenant (jg) on July 23, 1941; began active duty in the same rank on Sept. 10, 1941; commissioned a lieutenant (jg) in the medical corps of the U. S. Navy on Jan. 5, 1942; promoted to lieutenant on June 15, 1942; took his training at Corpus Christi, Texas, and flight training at Washington, D. C., and Pensacola, Fla.; served overseas at New Caledonia and Guadalcanal, attached to the 13th Marine Division as flight surgeon; awarded the Purple Heart; killed in action in the Pacific area Nov. 14, 1942, aged 27.

Louis Warren Streuter, Hamilton, Ohio; St. Louis University School of Medicine, 1940; interned at St. Louis City Hospital, where he served a residency; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on March 15, 1943; promoted to lieutenant; killed in action in the Philippines; aged 31; presumptive date of death Oct. 26, 1945, according to the U. S. Navy.

The Nostrum Evil

At the Hunterian Society an interesting debate took place on the nostrum evil. The motion was: "That the uncontrolled advertising of patent medicines is a menace to the public." The debate was led on the positive side by Mr. H. Linstead, secretary of the Pharmaceutical Society, and on the negative by a layman, Mr. Mortimer, director of a company which produces a well known proprietary medicine. In the course of the debate varying estimates were made of the amount spent annually on proprietary medicines. One physician said that as much as $36,000,000 a year was spent in advertising them, but Mr. Mortimer declared that the figure was much lower. The last published figure for the prewar year 1938 was $19,300,000 for all these preparations, including tonic wines, veterinary medicines and rupture appliances. The advertising space occupied no more than 8 per cent of the total advertising space in newspapers. But he admitted that his figures related only to advertising in the newspapers and took no account of advertising by posters on railways and other places or advertising by correspondence.

In the debate a curious sidelight was thrown on the working of national health insurance. It was seriously argued that physicians ought to be thankful to the manufacturers of proprietary medicines, for if they had to deal with all the persons who go to the pharmacist for something to relieve an ache or pain their surgeries would be choked with patients. They would have to see again all those whom they hoped they had seen for the last time. The advent of national health insurance apparently caused no falling off in the demand for proprietary medicines. One speaker, a physician, prophesied that under the proposed National Health Service, which covers all persons, the sales of proprietary medicines will be doubled or trebled. For this he gave the psychologic reason of the ineradicable conviction of most persons that what is not directly paid for is of no value. Thus he made apparent the great drawback of any "free to all" scheme. But one might go farther than this revelation of the debate. In spite of whatever relief the harasssed panel physician gets from the sale of proprietary medicines, much of his time is taken up by hypochondriacs and others with nothing the matter. In periods of stress they take up so much time that they limit his attention to cases of serious illness. Thus there are two opposite effects of the "free to all," but both can be traced to the craving for bottles of medicine, which an eminent surgeon of a former generation, Sir Frederick Treves, said was in this country "second only to the craving for strong drink."

Overseas Examinations by the Royal College of Surgeons

The Fellowship of the Royal College of Surgeons is the highest surgical qualification in the British empire and, though sought from all over the world, the examinations have always had to be taken in London. But the College has made a new departure. In response to requests from the Royal Australian College of Surgeons, the medical faculty of the Egyptian University, Cairo, and the Director General of Medical Services in India, the College will conduct the Primary Fellowship examination overseas. The following examiners have been appointed for the purpose: Sir Heneage Ogilvie, Prof. B. A. McSwiney, F.R.S., and Prof. G. Hadfield. They will conduct the examination in Cairo on December 12 and in Madras on December 23 and will begin in Australasia on January 6. The Australasian examinations will take place at Melbourne, Sydney and Dunedin. The examiners are expected to arrive back in this country about the end of January. The following associate examiners have been appointed to assist them: In Cairo, Prof. D. E. Derry and Prof. G. V. Anrep, F.R.S.; in India, Prof. A. A. Iyer; in Melbourne, Australia, Prof. S. Sunderland; in Sydney, Douglas Miller, and in Dunedin, John Carney.

The extent to which the new facilities offered to medical graduates of recognized universities overseas have been availed of can be judged by the numbers of candidates at the various centers: Cairo, 32; Madras, 65; Melbourne, 63; Sydney, 29, and Dunedin, 35. Those who satisfy the examiners will be eligible for the final Fellowship examination in this country and will have the opportunity to study surgical practice in England.

The Fatal Plastic Bib

A new danger to infant life, the result of technical progress which has given us plastics, is revealed by an inquest on a baby boy aged 3 months. An authentic account of the tragedy has been given in a letter to the *British Medical Journal* (November 23, page 804) by Dr. J. H. Fodden, pathologist to the Royal Salop Infirmary. The child was placed in his cot for sleep with a clean plastic bib tied loosely around his neck. The bib was small and was designed to fasten only around the neck with two pieces of tape. It was almost as thin as tissue paper and just as transparent. When the child was next seen he had been dead some hours. The thin plastic membrane covered his face almost as completely as did his skin. It took up every corner of his nose and mouth. The necropsy, which Dr. Fodden made, showed that the child had been asphyxiated. After he had warmed the bib in his hand for some time it seemed to become slightly "tacky." Then when placed over the child's face it spread quickly into the position of a close fitting mask. It is desirable that the warning of this tragedy should be widely circulated, as there may be millions of such bibs in use and on the market.

Labor Attempts to Coerce Nurses and Physicians to Join a Union

Since the return of the labor government the trade unions have become more aggressive. The latest manifestation of this is what is called "the closed shop" refusing, under the threat of a strike, to allow to work persons who are not members of a trade union. With the capture of many municipal bodies by labor, the way was opened for the rule that all the employees must be members of trade unions. The climax was reached when the matron, deputy matron, thirty-six nurses and one physician of the Willesden Municipal Hospital received notice of dismissal "in view of the fact that you have not complied with the council's resolution regarding membership of a trade union." Seventy nurses of Walthamstow received a similar notice that they must join a recognized trade union, and the same attempt at coercion has been made in other municipal hospitals. At Willesden the sister tutor and deputy matron had been serving the hospital for twenty-four years. Yet they were given a month's notice for a reason that had no relation to their capacity for their professional work. The answer of the nurses was an indignant refusal to comply with the order, and the council has begun to climb down. Unfortunately for them, there is a great shortage of nurses just now and if the nurses are dismissed probably none can be found to take their place. It is said that the council will recognize the Royal College of Nurses, to which most of the nurses belong, though this professional organization is not a trade union. Not only the press but the more wary tacticians who form the Labor Government have condemned the council for trying to coerce the nurses and not recognizing that the nursing of the sick is a primary matter which should come before politics. The British Medical Association is about to take action in the matter. The Secretary has declared that in the view of the British Medical Association no physician should be required to join any body, the British Medical Association or other.

MOSCOW

(From Our Regular Correspondent)

Oct. 12, 1946.

A New Method of Accelerating Labor

In 1945 Prof. R. Schub in the Central Institute of Gynecology and Obstetrics at Leningrad used thiamine hydrochloride for the first time as an anesthetic during labor. His method was tried in 900 cases; 250 pregnant women received vitamin B_1 as an anesthetic, and a control group of 200 pregnant women were anesthetized by other methods. All were completely examined, including multiple laboratory tests. Such detailed observations were not made on the remaining 450. The vitamin B_1 balance was studied during labor, post partum and in the puerperium, and the effects obtained were evaluated by special apparatus.

Anesthesia was begun simultaneously with active labor by intravenous, intramuscular and oral administration of 40 to 150 mg. of concentrated vitamin solution, each ampule containing 20 mg. of thiamine hydrochloride specially prepared by the All-Union Scientific Vitamin Institute. For oral use crystalline vitamin B_1 was taken.

The effect of intravenous administration was rapid but very short, and for this reason it was discontinued. Most active was the intramuscular administration of 60 mg. of thiamine hydrochloride. If pain appeared during parturition, a supplementary dose of 60 mg. of the drug was introduced. Anesthesia was observed in ten to fifteen minutes, and in 40 per cent of the
its effect was present till the end of labor. In 51.2
etic effect was short, and in 5.6 per cent
of vitamin B_1 was ineffective.

is not dangerous for mother or child. In a few
evanescent hyperemia was observed. Previous observa-
indicated that B-hypervitaminosis was seen only when
doses much larger than those of Professor Schub are used.

The administration of vitamin B_1 considerably ac
labor. *Its duration was half as long as usual.* A
explanation is as follows: Vitamin B_1 deficiency inh
phorus metabolism closely connected with the sy
carbohydrates which diminishes the energy reserves o

infected with South American Tr
agent of Chagas' disease. In
development of tumor wa
in the Soviet Medical
their experiments (stopped
in 1943) on other types of m

Experiments on more than 1
strated the existence of a specific t
animals which have not been inoculat
soma may be seen in the internal o
animals they are found principally in th
nosoma penetrate into malignant cells in
destruction beginning in the nucleus is obs
areas of destroyed malignant tissue increas
rounding all the neoplasm, and in their place
tissue forms.

The endotoxin of the trypanosoma has a great c
effect in different inoculated forms of experimental can
cancerolytic substance present in the trypanosoma body is soluble, stabile to acids and alcohol and may be filtered thro
Berkefeld L-3. It was demonstrated that this substance has cancerolytic effect on human malignant neoplasms and is innocuous even with prolonged subcutaneous or intramuscular administration. Sometimes a slight temperature reaction was observed, but it disappeared after the injections were finished.

This cancerolytic substance, named KR after the first letters of the investigators' names, was administered to 18 patients in the fourth stage of cancerous disease of the lips, larynx, breast and uterus. Such cases were selected because they permitted continuous observation of the action of KR. Destruction of the tumor was observed in 11 patients; 1 was made curable, and, following treatment with x-ray, the laryngeal tumor completely disappeared. In another case where the diagnosis was histologically confirmed, subcutaneous administration of KR caused the tumor to completely disappear. The patient has been under observation more than half a year and pathologic changes are absent.

The data demonstrate that the anticancerous substance of T. crusi has an elective cancerolytic action and simultaneously is innocuous to healthy tissues. Such eminent Soviet scientists as Petrov, Bogomolets and others appraise this work highly. At present Klujeva and Roskin are studying the disintegration of tumor cells, methods of obtaining a chemically pure preparation of KR, various forms of the cancerolytic substance and
stages of cancer.

Societies in the Soviet Union

Death of Alexander Bogomolets

The eminent Soviet pathologist Alexander A. Bogomolets died, July 19, 1946 at the age of 65. He was president of the Ukrainian Academy of Sciences, a member of the Presidium of the Soviet Union Academy of Sciences, a Stalin Prize winner and deputy of both Supreme Councils.

He graduated from the medical faculty in 1906, receiving his M.D. degree in three years. After studying physiology in Paris, he was elected, in 1912, professor of general pathology and bacteriology in the Saratov University. In 1928 he was appointed to the Chair of Pathology in the Second Moscow Medical Institute, and two years later he was elected president of the Ukrainian Academy of Sciences at Kiev. There he organized the Institute of Experimental Biology and Pathology, of which he was director until his death

Bogomolets wrote many scientific works and many were published by his famous school of pathophysiologists on such subjects as metabolism, allergy, nervous regulation of the vegetative functions, pathophysiology of hypertension and premature senility. The chief studies of Bogomolets and his collaborators concerned connective tissue, and they resulted in a method for treatment of various conditions by means of antireticular cytotoxic serum (ACS). This serum is made from the blood of horses which previously had received a spleen preparation that stimulates the activity of connective tissue. ACS helps in the healing of fractures, wounds and ulcers by improving the nourishment of cells.

The manual on pathophysiology written by Bogomolets is widely used by Soviet physicians and medical students. In a special decision, the Council of Ministers of the Soviet Union resolved that Bogomolets's name be honored at the Kiev Medical Institute and the Institute of Experimental Biology and Pathology. To perpetuate his memory an annual prize of 25,000 rubles ($5,000) is to be awarded by the Ukrainian Academy of Science. Thirty scholarships in his name are to be instituted for postgraduates, and his scientific work will be published by the Ukrainian Academy of Sciences during the years 1946 to 1948.

DENMARK

(From Our Regular Correspondent)

Copenhagen, Dec. 9, 1946.

The Danish Medical Association

A recent report on the activities of the Danish Medical Association, with a membership of 4,239, reveals a varied spectrum with helpfully disinterested advice at one end, gently chiding admonitions in the middle and stern disciplinary measures at the more somber end. Somewhere in the middle of this spectrum is the problem raised by a local branch of the association anxious to obtain from its central council a ruling on what part, if any, is to be played by the medical profession in beauty culture. It was asked, can a doctor act as judge at an examination conducted at an institute for beauty culture? The answer pointed out that though participation by the medical profession in the beautification of the nation is not directly prohibited by the rules of the association, such participation should be frowned at rather than smiled on, since some beauty experts have been tempted to puff themselves as having been "medically approved" in the sense that they have passed a medical examination on beauty culture. Among the instances requiring sterner measures is that of a physician who, during the occupation of Denmark by the Germans, acted as a locum tenens for a colleague in hiding from them. A rebuke was administered to the locum tenens for having exploited his colleague's embarrassment by exorbitant charges.

Supervision of Medical Notes in the Lay Press

During a general debate at a recent meeting of the Danish Medical Association, the suggestion was made that this body should appoint a press secretary to act as a watchdog on incorrect and misleading medical news in the lay press. The Danish Medical Association has for many years collected press cuttings, and the above suggestion aimed merely at extending this activity. The lack of enthusiasm for this suggestion was most effectively voiced by one speaker who said that a medical press secretary who attacked every little mistake in regard to medical matters in the lay press would succeed in making himself a nuisance without really helping to educate the public. An official denial appearing in the lay press would, as a rule, just draw attention to some trifle which the public had already forgotten. One the other hand, the editor of the journal of the Danish Medical Association (*Ugeskrift for læger*) Dr. Mogens Fog said he would like the lay press to be free to cull medical news from the medical press.

Fees for Locum Tenens

In 1939 a scale of charges for a locum tenens was drawn up by the Danish Medical Association with the intention of preventing abuses at either end of the scale. But since then terms have so often been agreed on between the interested parties without reference to the official scale that its further maintenance has seemed questionable. Not only has the Danish Medical Association often been left out of the picture altogether in negotiations between the contracting parties, but the journal of the Danish Medical Association has actually been employed as a medium for advertising locum tenens terms incompatible with the association's rules. To put an end to this unconstitutional state of affairs, the association has recently discussed two possibilities. The first and least attractive is to let the laws of supply and demand dictate terms. If this is done a locum tenens can force prices up when physicians are few and the other side can force prices down when physicians are many. The outcome of such a state of affairs would, in the opinion of the association, be so unsatisfactory that it would be wiser to adopt the second alternative and definitely to brand as unethical those agreements which fail to comply with the rules laid down by the association. However, it is pointed out that such rules should not apply to hospital appointments or to a specialist employing a locum tenens.

Responsibility for Appendicitis Mortality

Though Denmark has a population of only 3.9 millions, there were as many as 283 deaths from appendicitis in 1944. In the same year there were some 2,100 patients treated for appendicitis in the hospitals of greater Copenhagen. Among these patients there were 48 deaths, 28 due to peritonitis. Dr. Mogens Ingerslev of Surgical Department A at the Bispebjerg Hospital has recently undertaken an investigation of what befell the 221 patients with appendicitis treated in his hospital before Feb. 1, 1946. The title of his study, Responsibility for the Mortality of Acute Appendicitis, gives an accusatory tone to his study. He classifies his 221 patients according to the interval between the onset of pain and the request for medical aid. In 50 cases the correct diagnosis was not made at a physician's first visit, and these cases are classified according to the interval between the first and second visit of the physician. The 221 cases are also classified according to the general condition of the patient on admission to the hospital and the degree and localization of the pain. It was noteworthy that in as many as 71 cases there was a history of one or more previous attacks. The final conclusion to which Dr. Ingerslev comes is that appendicitis mortality is not going to be greatly reduced by sulfonamide preparations, penicillin and the like but by application of the three golden rules: early diagnosis, early admission to a hospital and early surgical intervention.

condemned the council for trying to coerce the nurses and not recognizing that the nursing of the sick is a primary matter which should come before politics. The British Medical Association is about to take action in the matter. The Secretary has declared that in the view of the British Medical Association no physician should be required to join any body, the British Medical Association or other.

A New Method of Accelerating Labor

In 1945 Prof. R. Schub in the Central Institute of Gynecology and Obstetrics at Leningrad used thiamine hydrochloride for the first time as an anesthetic during labor. His method was tried in 900 cases; 250 pregnant women received vitamin B_1 as an anesthetic, and a control group of 200 pregnant women were anesthetized by other methods. All were completely examined, including multiple laboratory tests. Such detailed observations were not made on the remaining 450. The vitamin B_1 balance was studied during labor, post partum and in the puerperium, and the effects obtained were evaluated by special apparatus.

Anesthesia was begun simultaneously with active labor by intravenous, intramuscular and oral administration of 40 to 150 mg. of concentrated vitamin solution, each ampule containing 20 mg. of thiamine hydrochloride specially prepared by the All-Union Scientific Vitamin Institute. For oral use crystalline vitamin B_1 was taken.

The effect of intravenous administration was rapid but very short, and for this reason it was discontinued. Most active was the intramuscular administration of 60 mg. of thiamine hydrochloride. If pain appeared during parturition, a supplementary dose of 60 mg. of the drug was introduced. Anesthesia was observed in ten to fifteen minutes, and in 40 per cent of the women its effect was present till the end of labor. In 51.2 per cent the anesthetic effect was short, and in 5.6 per cent the administration of vitamin B_1 was ineffective.

This method is not dangerous for mother or child. In a few cases, an evanescent hyperemia was observed. Previous observations indicated that B-hypervitaminosis was seen only when doses much larger than those of Professor Schub are used.

The administration of vitamin B_1 considerably accelerated labor. Its duration was half as long as usual. A physiologic explanation is as follows: Vitamin B_1 deficiency inhibits phosphorus metabolism closely connected with the synthesis of carbohydrates which diminishes the energy reserves of muscular tissue. The introduction of thiamine delays muscular fatigue, helps to store glycogen and thus forms an energy reserve. It accelerates contractions of the involuntary muscles having a direct peripheral effect as well as acting on the centers, as was demonstrated by Chochard.

This complex work of studying the action of vitamin B_1 during labor has only begun. It is headed by Prof. R. L. Lourje and P. L. Beloschaska in consultation with Prof. A. E. Mandelstamm, S. A. Jagunov and others. The scientific Medical Council of the All-Union Ministry of Health has proposed that the Leningrad, Moscow, Kiev, Voronesz and Sverdlovsk gynecologic and obstetric clinics study Schub's method, which opens new ways in the management of labor.

The Cancerolytic Substance of Trypanosoma Crusi

Recently Prof. Nina G. Klujeva, corresponding member of the Academy of Medical Science of the Union of Soviet Socialist Republics, and her husband, Prof. Gregory J. Roskin, presented at the meeting of the academy a report of their investigations begun in 1929 in which they had nearly 70 per cent of cures in adenocarcinomatous mice. After inoculation the mice were infected with South American Trypanosoma crusi, causative agent of Chagas' disease. In the remaining 30 per cent the development of tumor was delayed. These results were published in the Soviet Medical Press. Klujeva and Roskin continued their experiments (stopped during the war and taken up again in 1943) on other types of malignant tumors.

Experiments on more than 13,000 laboratory animals demonstrated the existence of a specific tumor trophism. In the control animals which have not been inoculated with the tumor, trypanosoma may be seen in the internal organs, while in cancerous animals they are found principally in the tumor tissue. Trypanosoma penetrate into malignant cells in which the process of destruction beginning in the nucleus is observed. As a result areas of destroyed malignant tissue increase, gradually surrounding all the neoplasm, and in their place new connective tissue forms.

The endotoxin of the trypanosoma has a great cancerolytic effect in different inoculated forms of experimental cancer. The cancerolytic substance present in the trypanosoma body is water soluble, stabile to acids and alcohol and may be filtered through Berkefeld L-3. It was demonstrated that this substance has a cancerolytic effect on human malignant neoplasms and is innocuous even with prolonged subcutaneous or intramuscular administration. Sometimes a slight temperature reaction was observed, but it disappeared after the injections were finished.

This cancerolytic substance, named KR after the first letters of the investigators' names, was administered to 18 patients in the fourth stage of cancerous disease of the lips, larynx, breast and uterus. Such cases were selected because they permitted continuous observation of the action of KR. Destruction of the tumor was observed in 11 patients; 1 was made curable, and, following treatment with x-ray, the laryngeal tumor completely disappeared. In another case where the diagnosis was histologically confirmed, subcutaneous administration of KR caused the tumor to completely disappear. The patient has been under observation more than half a year and pathologic changes are absent.

The data demonstrate that the anticancerous substance of T. crusi has an elective cancerolytic action and simultaneously is innocuous to healthy tissues. Such eminent Soviet scientists as Petrov, Bogomolets and others appraise this work highly. At present Klujeva and Roskin are studying the disintegration of tumor cells, methods of obtaining a chemically pure preparation of KR, various forms of the cancerolytic substance and its use in different stages of cancer.

Medical Societies in the Soviet Union

The All-Union Minister of Health has approved a new structure of scientific medical societies in this country. All-Union special societies will be organized. Medical societies of republics, regions and cities will be included, as well as existing All-Russian societies and associations.

A registration of all former and present members of scientific medical societies is being made. Scientific workers with a candidate's or doctor's degree who have been recommended by two society members may be elected. Physicians who have been practicing not less than two years and who have published contributions also may be elected members after recommendation by three members of the society. Physicians who are famous because of their scientific contributions or activity in health organizations may be elected honorary members.

The Soviet Union Scientific Medical Council of the Ministry of Health must work out in collaboration with All-Union Medical Societies the plan of their meetings and programs for 1947-1948 before Dec. 1, 1946. A committee for the guidance of medical scientific societies has been organized under the presidency of Prof. V. S. Preobrajensky, honorary worker of science.

Death of Alexander Bogomolets

The eminent Soviet pathologist Alexander A. Bogomolets died, July 19, 1946 at the age of 65. He was president of the Ukrainian Academy of Sciences, a member of the Presidium of the Soviet Union Academy of Sciences, a Stalin Prize winner and deputy of both Supreme Councils.

He graduated from the medical faculty in 1906, receiving his M.D. degree in three years. After studying physiology in Paris, he was elected, in 1912, professor of general pathology and bacteriology in the Saratov University. In 1928 he was appointed to the Chair of Pathology in the Second Moscow Medical Institute, and two years later he was elected president of the Ukrainian Academy of Sciences at Kiev. There he organized the Institute of Experimental Biology and Pathology, of which he was director until his death.

Bogomolets wrote many scientific works and many were published by his famous school of pathophysiologists on such subjects as metabolism, allergy, nervous regulation of the vegetative functions, pathophysiology of hypertension and premature senility. The chief studies of Bogomolets and his collaborators concerned connective tissue, and they resulted in a method for treatment of various conditions by means of antireticular cytotoxic serum (ACS). This serum is made from the blood of horses which previously had received a spleen preparation that stimulates the activity of connective tissue. ACS helps in the healing of fractures, wounds and ulcers by improving the nourishment of cells.

The manual on pathophysiology written by Bogomolets is widely used by Soviet physicians and medical students. In a special decision, the Council of Ministers of the Soviet Union resolved that Bogomolets's name be honored at the Kiev Medical Institute and the Institute of Experimental Biology and Pathology. To perpetuate his memory an annual prize of 25,000 rubles ($5,000) is to be awarded by the Ukrainian Academy of Science. Thirty scholarships in his name are to be instituted for postgraduates, and his scientific work will be published by the Ukrainian Academy of Sciences during the years 1946 to 1948.

DENMARK

(From Our Regular Correspondent)

Copenhagen, Dec. 9, 1946.

The Danish Medical Association

A recent report on the activities of the Danish Medical Association, with a membership of 4,239, reveals a varied spectrum with helpfully disinterested advice at one end, gently chiding admonitions in the middle and stern disciplinary measures at the more somber end. Somewhere in the middle of this spectrum is the problem raised by a local branch of the association anxious to obtain from its central council a ruling on what part, if any, is to be played by the medical profession in beauty culture. It was asked, can a doctor act as judge at an examination conducted at an institute for beauty culture? The answer pointed out that though participation by the medical profession in the beautification of the nation is not directly prohibited by the rules of the association, such participation should be frowned at rather than smiled on, since some beauty experts have been tempted to puff themselves as having been "medically approved" in the sense that they have passed a medical examination on beauty culture. Among the instances requiring sterner measures is that of a physician who, during the occupation of Denmark by the Germans, acted as a locum tenens for a colleague in hiding from them. A rebuke was administered to the locum tenens for having exploited his colleague's embarrassment by exorbitant charges.

Supervision of Medical Notes in the Lay Press

During a general debate at a recent meeting of the Danish Medical Association, the suggestion was made that this body should appoint a press secretary to act as a watchdog on incorrect and misleading medical news in the lay press. The Danish Medical Association has for many years collected press cuttings, and the above suggestion aimed merely at extending this activity. The lack of enthusiasm for this suggestion was most effectively voiced by one speaker who said that a medical press secretary who attacked every little mistake in regard to medical matters in the lay press would succeed in making himself a nuisance without really helping to educate the public. An official denial appearing in the lay press would, as a rule, just draw attention to some trifle which the public had already forgotten. One the other hand, the editor of the journal of the Danish Medical Association (*Ugeskrift for læger*) Dr. Mogens Fog said he would like the lay press to be free to cull medical news from the medical press.

Fees for Locum Tenens

In 1939 a scale of charges for a locum tenens was drawn up by the Danish Medical Association with the intention of preventing abuses at either end of the scale. But since then terms have so often been agreed on between the interested parties without reference to the official scale that its further maintenance has seemed questionable. Not only has the Danish Medical Association often been left out of the picture altogether in negotiations between the contracting parties, but the journal of the Danish Medical Association has actually been employed as a medium for advertising locum tenens terms incompatible with the association's rules. To put an end to this unconstitutional state of affairs, the association has recently discussed two possibilities. The first and least attractive is to let the laws of supply and demand dictate terms. If this is done a locum tenens can force prices up when physicians are few and the other side can force prices down when physicians are many. The outcome of such a state of affairs would, in the opinion of the association, be so unsatisfactory that it would be wiser to adopt the second alternative and definitely to brand as unethical those agreements which fail to comply with the rules laid down by the association. However, it is pointed out that such rules should not apply to hospital appointments or to a specialist employing a locum tenens.

Responsibility for Appendicitis Mortality

Though Denmark has a population of only 3.9 millions, there were as many as 283 deaths from appendicitis in 1944. In the same year there were some 2,100 patients treated for appendicitis in the hospitals of greater Copenhagen. Among these patients there were 48 deaths, 28 due to peritonitis. Dr. Mogens Ingerslev of Surgical Department A at the Bispebjerg Hospital has recently undertaken an investigation of what befell the 221 patients with appendicitis treated in his hospital before Feb. 1, 1946. The title of his study, Responsibility for the Mortality of Acute Appendicitis, gives an accusatory tone to his study. He classifies his 221 patients according to the interval between the onset of pain and the request for medical aid. In 50 cases the correct diagnosis was not made at a physician's first visit, and these cases are classified according to the interval between the first and second visit of the physician. The 221 cases are also classified according to the general condition of the patient on admission to the hospital and the degree and localization of the pain. It was noteworthy that in as many as 71 cases there was a history of one or more previous attacks. The final conclusion to which Dr. Ingerslev comes is that appendicitis mortality is not going to be greatly reduced by sulfonamide preparations, penicillin and the like but by application of the three golden rules: early diagnosis, early admission to a hospital and early surgical intervention.

POSITIONS IN PUBLIC HEALTH

To the Editor:—The practice of public health is becoming recognized as a specialty of medicine by both the profession and the public. The medical profession is taking the leadership in the promotion of adequate health departments staffed by well qualified, well trained people and is insisting that there be medical direction of these health departments. Government is recognizing the soundness of this principle and many recent appointments are evidence that government wishes to entrust the responsibilities for its public health only to physicians who are qualified by training and experience to assume the administrative position of health officer.

In The Journal, Dec. 22, 1945, page 1161, Dr. Thomas Parran, Surgeon General of the United States Public Health Service, pointed out the lack of qualified physicians in this specialty and emphasized the career opportunities available to young physicians who wish to practice this type of medicine. The New York State fellowship program is the result of recognition of the need for adequately qualified public health physicians to carry out the duties of full time health officers.

This training program consists of six or more months' field experience under the direct supervision of a medical health officer of the state department of health followed by an academic year at one of the postgraduate schools of public health. During the field training the physician on fellowship is afforded the opportunity to conduct epidemiologic investigations of outbreaks of communicable disease and to assist in the application of control measures. He observes and participates in community control measures, such as mass immunization or mass tuberculosis case finding. He ascertains the value of statistics in measuring the health of the community and the effectiveness of his work. He participates in the educational methods which are practiced to make the scientific aspects of preventive medicine applicable to every day community improvement of health. He is instructed in business and administrative principles and procedures necessary to carry on the functions of a well organized health department. Recognition is given to the need for correlation of the community practice of medicine by the health officer, with the clinical practice of medicine by the private practitioner. This period of field training is in effect a "residency in public health." After successfully completing this residency, he is enrolled in one of the schools of public health for one academic year, at the end of which he is eligible for the degree of Master of Public Health.

A careful selection of the applicants is made. The applicant for the fellowship must be a graduate of a school of medicine approved by the American Medical Association, must have served an internship of at least one year's duration in a hospital approved for such internship by the American Medical Association and must be licensed or eligible to take the examination for license to practice medicine in New York State. Some experience in the clinical practice of medicine is desirable but not required. He must be a citizen of the United States and should be not more than 35 years of age.

The fellowship is $295 per month for the field training period and either $200 or $300 per month during the academic training. The amount varies with whether or not the Fellow has dependents. Necessary travel and other expenses are paid by the department, and tuition at the school of public health is granted in addition to the stipend allowance.

Opportunities in the field of public health are greater than ever before. There are currently thirty-seven vacancies in state and local full time health officer positions in New York State, exclusive of New York City. Entrance positions in the New York State Department of Health carry a salary of $4,560 per year. Advancement within the department is usually rapid, and highly desirable positions in local health departments are usually filled from the staff of the state department of health. Full time local health officer positions in New York State pay an annual salary of $6,000 to $10,000. All appointments carry the benefits of civil service, including liberal vacation and sick leave and retirement income after the age of 60. Independent research in public health problems is an integral part of the activities of the department of health.

Thus an opportunity is offered to young physicians to enter public health as a career in New York State. Fellowships are still available and applications are invited. Now that physicians are returning from the armed forces and all new graduates of medical schools are no longer being taken into the Army and Navy, this unusual opportunity may not continue much longer. Further information can be obtained on application.

Franklyn B. Amos, M.D., Albany, N. Y.
Secretary, Executive Committee on Recruitment
and Training of Medical Personnel, Department
of Health, State Office Building.

THE PHYSICIANS' DESK REFERENCE OF MEDICAL ECONOMICS

To the Editor:—You probably have received a copy of the Physicians' Desk Reference Book to Pharmaceutical Specialties and Biologicals for 1947, published by Medical Economics, Inc., Rutherford, N. J.

You will certainly be interested in reading the letter which I have written to the editor and of which I am enclosing a copy.

Being a neurologist, I just happened to mention two conditions which affect my own field of work. But I feel sure that the observation could be duplicated many times.

Karl Rothschild, M.D., New Brunswick, N. J.

The letter follows:

> I have received your Physicians' Desk Reference Book and I want to compliment you on the general excellence of the presentation of material.
>
> Permit me, however, to make a few remarks which I think are of importance:
>
> I had the opportunity to look into the blue section under the heading of Myasthenia Gravis. If the index is worth anything, it should certainly mention Prostigmine as the primary and, as I believe, the *only* remedy for this disease, the other mentioned therapeutic measures being at best only adjuvants. *In fact* the Intocostrin (Squibb) is definitely contraindicated and if you will look up the white section of the book you will find that it is recommended as a test in judicious hands only. An inexperienced reader might certainly be very much misled. I feel that the words "for testing" should be added to the listing on page 201.
>
> In the same way, under Narcolepsy I miss any mention of Benzedrine, which certainly is known as the primary therapeutic agent for this disease.
>
> The fact that the firms of Hoffmann-La Loache and Smith, Kline and French have not contributed to the white section *should, in my opinion,* not prevent you from being fair and giving the doctors a true picture of the pharmaceutical specialties in the proper indications.
>
> A thorough revision of the P. D. R. in this respect will be absolutely necessary if the index shall serve the purpose to which you lay claim.
>
> Karl Rothschild, M.D.

DENTAL BENEFITS UNDER COMPULSORY INSURANCE

To the Editor:—In the British *Dental Magazine and Oral Topics* (**63:**206 [Oct.] 1946) the following interesting item occurs:

> In Great Britain a committee had gone into the question of dental benefit under the British National Health Insurance Act, and the following was a quotation from their report:
>
> "Roughly two thirds of the insured population, that is, between thirteen and fourteen million people, are entitled to dental benefit, but only 800,000 (less than 7 per cent) of these claim it on an average each year."

It has always been my contention that making health services available and "free" is not enough. In our small health department clinics here in Birmingham we have to police some 10,000 syphilitic patients every year to make them return to the clinics and take at least the minimum required treatments. Our first duty seems to be to teach the public the value of health. Were it deemed as valuable as liquor, tobacco, cosmetics or stainless steel jewelry, its availability would be certified. What socialized medicine wouldn't do for people, and what it would do to them still has not been made plain to the public at large.

The magazine also contains (p. 176) a most amusing forecast of British dentistry in the form of pages from a dentist's diary in 1961, strangled in red tape regulations.

Daniel W. Josselyn,
408 Broadway, Edgewood,
Birmingham 9, Ala.

INTRAUTERINE RESPIRATION OF THE FETUS

To the Editor:—We are interested in the paper of Davis and Potter on "Intrauterine Respiration of the Human Fetus" which appeared in The Journal August 10. On the basis of our own experiments of this nature we feel that the evidence which they present fails to be convincing on at least three counts:

First, the proponents of the thesis that the fetus normally aspirates amniotic fluid in utero cite Ahlfeld's early paper on the observability of fetal respiratory movements through the intact maternal abdomen during the later stages of pregnancy. Yet rarely does an obstetrician encounter this phenomenon. If the authors themselves observed such movements in their own series, they fail to report them. It is our belief that if and when movements are observable the fetus may be in a state of mild anoxic distress. May it be that their late fetuses did not execute respiratory movements until the time of operation?

Secondly, the experiments lack sufficient controls. In 3 of the 4 control fetuses the authors failed to observe the presence of thorotrast in the respiratory tract; however, it is interesting that these controls were as small as or smaller (7.5 to 12 cm. in length) than the youngest fetus in which thorotrast was found in the lungs. The authors indicated the necessity for adequate concentration of thorotrast in the amniotic fluid in order to produce a visible lung shadow, yet in this control series the dilution was at its lowest level (12 cc.). In the youngest fetus showing good shadows, 35 cc. was used. They are not justified in concluding that the presence of thorotrast in the lungs is unrelated to the experimental or operative procedures.

In the third place, they failed to do the one thing which would have provided the best answer to their question and would have made their case more convincing had they then observed thorotrast in the fetal lung. They did not take roentgenograms of the fetus at regular intervals through the intact maternal abdomen. Knowing that it takes very little operative handling to disturb blood-gas relationships in animal fetuses in utero, we are inclined to believe that the aspiration observed by the authors occurred only during operation or delivery at cesarean section.

Our own experiments indicate that, when one clamps the trachea of an animal fetus immediately on incising the uterus, the histologic picture of the lungs of such fetuses is entirely different from any of the histologic pictures presented in this article (see paper by Whitehead, Windle and Becker, *Anat. Rec.* **83**:255 [June 25] 1942). The lung of the normal apneic fetus is apparently in complete atelectasis with unexpanded respiratory bronchioles, alveolar ducts and alveolar sacs. On the other hand, we do find amniotic contents aspirated and the respiratory passage dilated whenever any factor, even very slightly, intervenes at operation to alter the blood-gas relationships sufficiently to stimulate the respiratory center and initiate respiratory movements in amnio.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, Jan. 4, page 59.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, Jan. 21-23. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

Arkansas: * *Medical. Examination.* June 5-6. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 5. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination.* Los Angeles, March 10-13. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Connecticut: * *Medical. Examination.* Hartford, March 11-12. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, March 11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

Delaware: *Examination.* Dover, Jan. 14-16. *Endorsement.* Dover, Jan. 21. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

Georgia: Atlanta and Augusta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Hawaii: Honolulu, Jan. 13-16. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, Jan. 14. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

Illinois: Chicago, Jan. 28-30. Supt. of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Maine: Portland, March 11-12. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

Massachusetts: Boston, March 11-14. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston 33.

Minnesota: * Minneapolis, Jan. 21-23. Sec., Dr. J. F. Du Bois, 230 Lowery Medical Arts Bldg., St. Paul 2.

Missouri: *Examination:* Kansas City, Jan. 27-29. Exec. Sec., Department of Education, Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

Montana: Helena, April 1-2. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

Nebraska: * *Examination.* Omaha, June 1947. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

Nevada: *Examination.* Carson City, May 5. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Hampshire: Concord, March 13. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, April 7-8. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

New York: Albany, Buffalo, New York and Syracuse, Jan. 27-30. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, Jan. 16. Act. Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

Oklahoma: * *Reciprocity.* Oklahoma City, Dec. 29-30. Sec., Dr. J. D. Osborn Jr., Frederick.

Oregon: * Portland, Jan. 22-25. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.

Pennsylvania: Philadelphia and Pittsburgh, July. Acting Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Rhode Island: * Providence, Jan. 2-3. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota: * Pierre, Jan. 21-22. Sec., Dr. Gilbert Cottam, State Capitol Bldg., Pierre.

Texas: *Examination.* Galveston, Feb. 20-22. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

Vermont: *Examination.* Burlington, Jan. 31-Feb. 1. Sec., Board of Medical Registration, Dr. F. J. Lawliss, Richford.

Washington: *Examination.* Seattle, January 1947. Sec., Mr. Nelson Vaughn, Olympia.

Wyoming: Cheyenne, Feb. 3. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Connecticut: Feb. 8. Address State Board of Healing Arts, 250 Church St., New Haven.

District of Columbia: Washington, April 21-22. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: May 31. Sec., Dr. M. W. Emmel, University of Florida, Gainesville.

Iowa: Des Moines, Jan. 14. Corresponding Sec., Division of Licensure & Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

Nebraska: Omaha, Jan. 14-15. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln 9.

New Mexico: Santa Fe, Feb. 2. Secretary, State Capitol, Santa Fe.

Oregon: Portland, March 1. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: Providence, Feb. 12. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Revocation of License After Conviction for Rape.—The South Carolina State Board of Dental Examiners alleged that the defendant had been guilty of immoral or dishonorable conduct and asked that his license to practice dentistry be revoked. From a judgment in the trial court in favor of the defendant, the State Board of Dental Examiners appealed to the Supreme Court of South Carolina.

The defendant was licensed to practice dentistry in 1937, and he practiced his profession in South Carolina until September 1943, when he was convicted of rape, sentenced and later pardoned The defendant admitted that he had been convicted of rape but denied that he was guilty. At the trial the Board offered in evidence the indictment, the verdict of guilty endorsed thereon and the sentence imposed by the court. A resolution of the Dental Board stating that on the record of the conviction the Dental Board believed that the defendant "has been guilty of immoral and dishonorable conduct which would prevent it from issuing to him a certificate to practice" was also offered in evidence. Oral evidence was introduced from various officers of the Dental Board to the effect that a license to practice dentistry would not have been issued to the defendant in the first instance had he been previously convicted of rape as shown by the court record.

The defendant first argued that a judgment in a criminal prosecution cannot be received in a subsequent civil action to establish the truth of the facts on which it was based and contended, therefore, that he was entitled to a trial *de novo.* While some courts have rigidly adhered to such general rule, said the Supreme Court, many others have relaxed or modified the rule in certain cases to the extent of permitting the introduction of the criminal conviction as prima facie evidence of the facts involved, and in at least one jurisdiction the judgment of conviction has been held to be conclusive. Continuing, the Court said that the state has a right under its police power to define the qualifications one shall possess in order to engage in the practice of dentistry and, in doing so, may properly require that such a person not only possess the necessary technical skill but also the qualifications of honor and good moral character. Proceedings to revoke a professional license are not an effort to further punish for the same offense one who may already have been punished but are a rightful exercise of the power of the state to protect its citizens from practitioners who do not possess the necessary qualifications. For all practical purposes, said the Supreme Court, the parties in the present proceeding are the same as those in the criminal proceeding. The defendant has had his day in court and has been convicted with all the safeguards thrown around a person accused of crime. The question of his guilt here is precisely the same as it was when determined adversely to him under circumstances most favorable to himself—that is, in a prosecution in which he could not have been convicted unless his guilt had been shown beyond a reasonable doubt. The reasons generally assigned for not giving a judgment of conviction conclusive effect have no application to the instant case, and no good reason appears why defendant should not now be permitted to collaterally attack the judgment of conviction.

The defendant next argued that the Dental Board possesses no inherent power to revoke the license of a dentist. The Dental Practice Act empowers the circuit judge to revoke or suspend the license of a dentist who "has been guilty of any immoral or dishonorable conduct which would prevent the board, in its sense of honor, from issuing the certificates of practice provided for" in section 5199. When one has been duly convicted in the court of general sessions of a felony, we do not think, said the Supreme Court, that the statute contemplates that his guilt or innocence shall again be determined by the circuit judge in a revocation proceeding. If the defendant was now applying for a license to practice dentistry and possessed all the necessary professional skill, but some years previously had been convicted of rape, it would not be necessary for the Dental Board, a body wholly unlearned in the law and in legal procedure, to disregard the solemn adjudication of guilt made by the court of general sessions, the regular tribunal established under the constitution of this state for the trial of such cases, to try the case again and determine anew the defendant's guilt before it would be warranted in declining to issue a license on the ground that the applicant did not possess the necessary moral character. The conviction is evidence, and we think conclusive evidence, that the defendant did commit the offense.

Finally the defendant takes the position that neither the Dental Board nor the court is authorized under section 5210 to revoke a license to practice dentistry on the sole ground that the holder of the license has been convicted of a crime involving moral turpitude. The point is emphasized that the statute does not use the word "convicted," but reads "has been guilty of any immoral or dishonorable conduct." It may be that the legislature, in framing the statute in question, chose the word "guilty," instead of "convicted," so as to include as a ground for removal or suspension "immoral or dishonorable conduct" of such nature that it would not constitute an indictable offense. But whether or not this was the legislative intent we need not now decide, for manifestly it was intended to include such "immoral or dishonorable conduct" as rape, a felony at common law. We think, said the Supreme Court, the defendant's suggested construction of the statute is illogical and unreasonable and, if adopted, would lead to a result which obviously was not intended by the legislature.

In conclusion the Supreme Court said that another hearing before the circuit judge should be held, at which it will be conclusively presumed that the defendant "has been guilty" of rape. Such constitutes a proper ground for the revocation or suspension of his license. At such hearing, the court continued, the circuit judge will determine whether the defendant's license should be revoked or whether it should be suspended; and if he concludes there should only be a suspension, he shall further determine and fix the term of such suspension. Accordingly, the judgment in favor of the defendant was reversed and the cause remanded.—*South Carolina State Board of Dental Examiners v. Breeland, 38 S. E. (2d) 644 (S. C., 1946).*

Food and Drug Acts: Drugs Misbranded by Accompanying Circular.—The defendant was found guilty of misbranding his drugs in violation of the Federal Food, Drug and Cosmetic Act, and judgment was entered by the district court, S.D. California, central division.

The drugs involved in this case were shipped in interstate commerce on April 25, 1944. However, descriptive leaflets and circulars concerning the material, which amounted to a misbranding of the drugs, had been shipped in interstate commerce the preceding February. The circulars and the drugs had a common source and common destination and were subsequently displayed together. The sole issue, said the court, is whether the drugs and leaflets accompanied each other within the purview of the food and drug act.

In a prior case, the United States circuit court of appeals said:

> The word "accompany" is not defined in the Act, but we observe that among the meanings attributed to the word are "to go along with," "to go with or attend as a companion or associate" and "to concur in association with," Webster's New International Dictionary, 2d Ed.

The food and drug act, continued the district court, has always been liberally construed to protect the consuming public from the avaricious. Prior cases indicate that the courts have not applied the usual rule of strict construction of criminal statutes to this act but have given it a liberal construction and thus enabled the act to accomplish its remedial purpose of protecting the public's health and pocketbook against misbranded foods and drugs. I hold, the court concluded, that the word "accompany" as used in the act means that when a drug and a related circular, having a common source and a common destination, come together at their destination, they are united and become one in so far as the buying public is concerned, each, in effect, accompanying the other, whether they arrived at their common destination simultaneously or otherwise. Accordingly the defendant was found guilty of misbranding a drug contrary to the federal food, drug and cosmetic act.—*United States v. Alberty, 65 F. Supp. 945 (Calif., 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cardiovascular Defects in Selective Service Registrants. R. H. Eanes, K. H. McGill and M. L. Clark.—p. 504.

Influence of Age on Blood Pressure.—Russek and his co-workers analyzed the blood pressure of 5,331 men between the ages of 40 and 95. They found that normal systolic blood pressure tends to increase with age. The frequency of upper levels of "normal" (140 to 149 mm.) rises appreciably with advancing years. The assumption that normal diastolic blood pressure increases with age is unfounded. Actually a progressive decrease occurs with succeeding decades. The rise in normal systolic pressure and concomitant fall in normal diastolic pressure are primarily the result of progressive diminution in the elasticity of the aorta and its large branches (vascular factor). Physiologic changes in the central nervous system leading to vascular hyperreactibility with advancing years similarly exert an important influence on the blood pressure trends (neurogenic factor). Both mechanisms (vascular and neurogenic) are summated in their effect on systolic blood pressure while exerting opposing influences on diastolic blood pressure. Although the ceiling for normal diastolic blood pressure has been set at 90 mm. of mercury, an even lower level appears applicable after middle age.

Disadvantages of Thiouracil Treatment of Angina Pectoris.—DiPalma and MaGovern employed thiouracil in the treatment of 8 nonhypertensive cardiac patients with anginal pain, all but 1 of whom had normally functioning thyroids. In 4 patients the thiouracil treatment was stopped after less than two months because of toxic skin rashes, severe dyspnea and failure to lower the basal metabolic rate. No benefit on either precordial pain or exercise tolerance was experienced by these 4 patients. The 4 remaining patients were treated for over a year. In general, precordial pain was beneficially affected, at least for a time; at certain times exercise tolerance was doubled and even quadrupled. However, all except 1 lost the increased ability to do work at the end of the one year period. One patient had symptoms resembling coronary occlusion. The disadvantages of thiouracil in patients with normally functioning thyroid glands include toxicity, necessity of close supervision, inability to lower the metabolism, tendency toward water retention (which is deleterious to cardiac patients) and necessity of continuous therapy. Thiouracil is not recommended for angina pectoris as a routine procedure but only when the metabolic rate is elevated.

Folic Acid in Macrocytic Anemias.—Berman and his associates used synthetic folic acid in treating 11 patients with macrocytic anemia. They found that those with megaloblastic bone marrow responded to folic acid therapy, but those with normoblastic bone marrow did not respond. They present morphologic criteria for distinguishing megaloblastic from normoblastic erythropoiesis and discuss the chemical and physiologic differences between megaloblasts and normoblasts. Recognition of the presence or absence of megaloblastic development of erythrocytes in the marrow will make it possible to foretell which patients will respond to folic acid.

*Pyrosis: Analysis of Its Clinical Significance and Pathogenesis. G. W. H. Schepers.—p. 333.

Proctalgias and Perianal Dyscrasias.—Granet discusses several anal or rectal syndromes not of neoplastic or inflammatory origin. He mentions among others the relationship of coccygodynia to spastic contraction of the muscles attached to the coccyx and in some instances to a bursitis involving these muscles. Treatment by massage of the spastic muscles results in rapid relief of pain and muscle relaxation. In proctalgia fugax attacks of pain are sudden, sometimes awakening the patient out of sleep. Spasm in the region of the rectosigmoidal junction is suggested as the cause, and its psychosomatic nature seems well established. Glyceryl trinitrite or similar antispasmodics may prove effective in therapy. Chronic recurrent anal pruritus occurs in individuals with personality difficulties. This type of neurogenic pruritus may yield to psychotherapy.

Pyrosis.—Schepers reviews the clinical features observed in 100 patients in whom pyrosis was a chronic complaint. He was able to distinguish at least three pathologic conditions which are interdependent in respect to pathogenesis or etiology. In 50 per cent of the cases the endocrine dysfunction could be regarded as the major condition, pathologic change in the urinary tract was the basic feature in 38 per cent, and in the remaining 12 per cent alimentary tract disease could be incriminated. The author argues that pyrosis may represent a variety of visceral paresthesia referred to the gastric terminals of the splanchnic or the vagal nerves and localized and exteriorized to the terrains of the seventh, eighth and ninth thoracic somatic nerves through the central association between the greater sphlanchnic nerve and the corresponding spinal segments. In this series of cases it was associated with peripheral paresthesias, which responded to the same treatment as that which alleviated the pyrosis.

Folic Acid (Synthetic L. Casei Factor) a Panhematopoietic Stimulus.—In analyzing clinical and experimental studies with folic acid as derived from spinach, liver, yeast, other natural sources and now the synthetic Lactobacillus casei factor, Doan found that it becomes increasingly apparent that we are dealing with one of the more fundamental molecules essential to the normal metabolism of all cell types in marrow and in young, actively growing cells and tissues generally. In the absence of "sufficient" L. casei factor due to extrinsic dietary deprivation or with intrinsic interference in absorption, a cellular inadequacy develops in mammalian bone marrow. Many other factors, including infections, modify the relative clinical stability or instability of each human organism. The physician must search for the "balance of power" among the knowable factors in the equation, and when this is done the problem can be solved.

Kahn Test for Syphilis in Healthy Men.—A survey has been made of the meaning of 783 positive reactions to the Kahn standard serologic test for syphilis encountered in a population of 82,070 consecutively examined male maritime enrollees aged 16 to 54. Study of the men with positive serums indicated that 40 per cent had single positive reactions of questionable authenticity, 13 per cent had nonsyphilitic persistently positive reactions, 7 per cent had congenital syphilis and 40 per cent had acquired syphilis. Thus in one laboratory the detection of a positive or doubtful response to a Kahn standard serologic test led to the diagnosis of syphilis in 47 per cent, or less than half, of a group of healthy American men. Weakly positive reactions proved to mean syphilis in only 20 per cent of the group, whereas strongly positive reactions proved to mean syphilis in 80 per cent of the group.

Decline of Acute Surgical Mastoiditis. N. D. Fabricant.—p. 506.

Addison's Disease in the Negro.—Conn and Mathews think that the occurrence of Addison's disease in the Negro is far greater than is indicated by the few cases reported in the literature. It is easily understandable that when dealing with Negro patients the possibility of Addison's disease would suggest itself less frequently than in the case of white persons, since pigmentation of the skin is usually one of the most striking manifestations of the disease. The authors report the occurrence of Addison's disease in 5 Negroes and stress that physicians should be on guard for the recognition of this disease in Negroes.

Agglutination Inhibition Test in Vaccination Against Influenza.—Immunologic data were obtained by Florman and his co-workers with the aid of an agglutination-inhibition test from 89 persons who had been given a concentrated influenza virus vaccine containing two type A (PR-8 and Weiss) strains and one type B (Lee). This information was analyzed in relation to clinical observations associated with the administration of the vaccine. Almost two thirds of the group complained of either local or systemic reactions shortly after vaccination. However, these symptoms did not seem to be the result of an antigen-antibody reaction involving agglutination-inhibition antibody. Two serologically proved instances of type B influenza infection occurred during the fifth week following vaccination. Both were in men who had not produced high levels of antibody for the B component of the vaccine. Agglutination-inhibition antibodies for the type A viruses tended to appear earlier than for type B. Administration of the vaccine did not change the Kahn flocculation serologic test for syphilis reagin titer in the 59 persons so studied. Three weeks after vaccination 83 (93 per cent) of the group had developed fourfold or greater rises in antibody for at least one component of the vaccine. The serums were also tested against recently isolated type A and type B viruses (Olsen and Saha). The results indicated either that the Saha strain is antigenically more nearly like the Lee than the Pr-8 and Weiss are like the Olson or that the antibody response evoked by the Lee virus is immunologically broader than that of the A strains in the vaccine. Among those who responded to the vaccine there were some who did so to all the components of the vaccine, some who did so only to certain ones and a few who did not produce antibodies to the viruses in the vaccine as well as they did for the related Olson and Saha strains. The unpredictability of this phenomenon presents a serious problem if the level of circulating agglutination-inhibition antibody produced is indicative of the amount of protection against infection afforded by a vaccine.

Late Neuronitis Following Diphtheria.—Sampson presents observations on 20 cases of late polyneuronitis which developed from one to three months after proved or suspected cutaneous or faucial diphtheria. This syndrome differs from the early diphtheria neuritis which occurs during or within the first month after the attack of diphtheria. Fifteen of the 20 patients had acquired the pharyngeal or cutaneous diphtheria in the Southwest Pacific. The initial symptoms usually were numbness and paresthesias of the hands and feet. Partial electrical reactions of degeneration of the involved muscles were obtained in all the severe cases. The segmental character of motor and sensory involvement, generally C_1 to T_2 and L_3 to S_1 during the early and most severe stages of the disease, receded to signs of irregular distal peripheral neuritis. Recovery was generally abrupt, and the commonest residual signs after four to seven months' observation were absent achilles and patellar reflexes and diminished vibratory sense in the toes. Massage and passive and active exercises throughout the course of the disease apparently hastened the return to normal motor function and prevented muscle atrophy.

Needle Biopsy of Liver.—Needle biopsies of the liver have been done on 68 patients in the Cleveland City Hospital since 1939. Biopsies have been most useful in the diagnosis of cancer of the liver and in establishing the nature of diffuse parenchymal liver disease, including cirrhosis. Fatalities were not observed in this series.

Relationship of Maternal Weight Gain to Weight of Newborn Infant.—Klein studied 567 cases and found no correlation between the maternal weight gain during pregnancy and the weight of the baby at birth.

Adenomyosis of Uterus.—Spatt presents observations on 52 cases of adenomyosis uteri in which the endometrium was carefully examined, and he also reviews the literature. He concludes that adenomyosis uteri occurs in 5 to 10 per cent of all myomatous uteri. Like endometrial hyperplasia, it is most common in the fifth decade of life. Metromenorrhagia and dysmenorrhea are the most frequent complaints in adenomyosis uteri. Some patients have both these complaints. The sustained interval nonsecretory endometrium is a part of the process leading to endometrial hyperplasia. The early interval endometrium seems to occur in younger women and endometrial hyperplasia in older women. Adenomyosis is associated with anovulatory menstrual cycles in a large percentage of cases, indicating that either hyperestrinism or lack of corpus luteum hormone is an important factor in the genesis of adenomyosis uteri. It cannot be said definitely which one is responsible. The high incidence of fibroids in adenomyosis uteri seems to indicate some relationship; however, this association is not frequent enough to suggest that one factor is responsible for both.

Saddle Block Anesthesia.—The term saddle block anesthesia is applied to anesthesia confined exclusively to the perineal area. Parmley and Adriani used it with gratifying results in 135 normal primiparas or multiparas. They describe the technic for producing prolonged anesthesia and analgesia by using nupercaine. The ease and simplicity of induction, the safety allowed by the low dosage of the drug and the exact localization of the distribution of anesthesia make the use of this block the technic of choice where spinal anesthesia is preferred or desired in obstetrics.

Early Puerperal Rising.—The routine by which King prepared 221 women for early puerperal rising included standing for one minute the first day post partum, sitting in a chair for five minutes the second day, abdominal exercises in bed, and two five minute sitting periods the fourth day, walking about and toilet privileges on the fifth or sixth day, a shower the seventh day and discharge from the hospital on the eighth day when desired or necessary. The incidence of complications, subinvolution, prolonged lochia rubra, episiotomy breakdown, infections and uterine retroversion was not greater than usual. It is felt that early puerperal rising in uncomplicated cases of childbirth is desirable and without danger or unfavorable sequelae.

Early Rising and Morbidity in Cesarean Section.—Headings and Palmer found that when patients who had undergone cesarean section were allowed out of bed early the morbidity was only 2.8 per cent, compared with 9 per cent when early rising was not encouraged. No complications developed from the routine practice of getting all patients out of bed on the first postoperative day. Early rising allows full use of the available hospital facilities. The patients are grateful not only for lessened expense but also because of the definite improvement in the postoperative sense of well-being and avoidance of the weakness so noticeable in patients kept in bed twelve or fourteen days.

New Drugs in Epilepsy Therapy.—The first of the two drugs which Lennox says *increase the range and the effectiveness* of the control of epileptic seizures is Tridione. This drug has proved peculiarly effective in the control of seizures of the petit mal type: pyknoepilepsy, myoclonic jerks and akinetic epilepsy. Eighty-four per cent of the patients with petit mal were to some degree better. In contrast, grand mal convulsions were not helped or made worse. Psychomotor seizures were occasionally aided by Tridione combined with an anticonvulsant drug. The second drug, methyl phenyl ethyl hydantoin (Mesantoin), did not help petit mal, but in approximately one third of patients subjected to frequent major seizures it has replaced diphenyl hydantoin sodium (Dilantin) with profit. The benefit resulted either from a reduction in the frequency of convulsions or from an absence of the unpleasant side effects of either muscular incoordination or gum hypertrophy. Generalized rash or somnolence were side effects which limited the usefulness of the drug in many instances.

Transitory Schizophrenias in Bromide Intoxication.—According to Levin, bromide intoxication produces a variety of psychiatric syndromes. A new syndrome is described by the author on the basis of 13 cases. This is a psychosis of predominantly paranoid coloring which, to the examiner who does not know the history and laboratory findings and has not yet seen the outcome, has all the earmarks of an "ordinary" paranoid schizophrenia, from which it differs only in that it is a transient psychosis which has supervened during bromide intoxication and clears up fairly soon after discontinuance of the drug.

DDT for Pediculus Capitis in School Children.—*According to Kaiser pediculosis may be one of the greatest causes of absenteeism in schools. To simplify the treatment a preparation of* DDT powder (10 parts of DDT and 90 parts of inert powdered talc) was sprayed on the child's hair, a paper towel being placed over the eyes to prevent irritation. The head was kept covered until bedtime. In the morning the hair was combed with a fine comb to remove the dead lice and as many eggs as possible. On the seventh day another application of DDT powder is made, following a shampoo on the previous evening. At the end of the second week another application of DDT is made if necessary. Thus far 350 children have been treated with this method.

Porencephaly.—The 29 cases of porencephaly reviewed by Pendergrass and Perryman were all studied by encephalography and/or ventriculography, and in 16 craniectomy was done. Unilateral change in the thickness of the skull was the most common observation in the conventional roentgenograms of patients with porencephaly. The various types of porencephaly have been classified as "lobe," "interlobe" and "hemisphere." Cortical or subcortical atrophy, enlargement of the ventricles and arachnoiditis were found in association with porencephaly and may be contralateral, homolateral or bilateral and localized or generalized. There was usually a slight shift of the ventricles and midline structures more often to the same side but frequently to the opposite. Porencephaly must always be considered in the differential diagnosis of mass, cystic and contracting lesions involving the brain.

Secondary Myelofibrosis.—Bersack and Feinstein's patient was a man aged 55 who had secondary myelofibrosis with generalized osseous eburnation as a result of skeletal metastases of prostatic carcinoma. Only 2 similar cases have been presented in the English literature. The prognosis in such cases is worse than in the average carcinoma of the prostate. The course varies between one and one-half years. Myelofibrosis has two prerequisite elements; namely, destruction of bone marrow and an attempt at compensation by the remaining hemopoietic tissue, inclusive of metaplasia in the spleen and the liver. The cardinal symptoms are weakness, bone pains, a varying degree of splenomegaly and a refractory anemia with nucleated red blood cells and immature white blood cells in the peripheral blood. Histopathologically the involved bone shows an increase in width and number of the trabeculae, with linear calcium deposition. The lamellae present normal lacunae and bone cells. A conspicuous feature is the scarcity or complete absence of lining osteoblasts and osteoclasts. The marrow spaces contain fibrous tissue with sparsely scattered infiltrative foci of tumor cells.

Treatment of Cervical Cancer.—Taylor and Twombly divided all cases of primary cervical cancer observed in their gynecologic clinic during 1943 and 1944 into two equal and comparable groups. One group was treated with divided dose roentgen therapy to the pelvis and intravaginal roentgen therapy to the parametria and cervix through special cones. This program of roentgen therapy was followed by intracervical radium. The second group also received divided dose external roentgen therapy and intracervical radium, but the intravaginal roentgen treatments were replaced by interstitial radon therapy delivered by means of needles inserted into the parametria at the time the radium was applied to the cervical canal. The patients treated with needles had more severe rectal symptoms, more bladder symptoms and more local necrosis, hemorrhage and pain than did those treated with vaginal cones. Furthermore, the mortality was greater in those treated with needles, and the authors have abandoned this treatment in favor of the other one.

Sulfhydryl in Treatment of Corneal and X-Ray Burns.—A study based on five years of clinical application of a sulfhydryl therapy in more than 500 cases of burns involving the eyes and adjacent areas has convinced Cruthirds that the danger of scarring may be greatly reduced. The product used, hydrosulphosol, presents sulfur in a "free" colloidal state with a high concentration of sulfhydryl suggesting availability of sulfur in a form that can be utilized by the body in the synthesis of sulfur-containing amino acids. Sulfur-containing compounds constitute almost one half of the mineral content of the lens and are connected with tissue respiration, oxygen transport, detoxication, capsular permeability, protein synthesis and general metabolic efficiency. In conjunction with penicillin, hydrosulphosol has proved effective also in corneal ulcers with results not observed with penicillin alone. There has been no evidence of toxic reactions following free and repeated application of this sulfhydryl bearing solution. Hydrosulphosol is superior to other methods in its ability to heal x-ray burns in that it heals with less chance of development of symblepharon, and it heals faster and without scarring and infection. The application of a 1:1 spray of hydrosulphosol solution establishes quickly a dry, flexible coating. This coating has proved to be the only covering needed.

Ectopic Pregnancy in Cervical Mucosa.—Schneider reviewed the literature since 1926 and found that in only 10 of 30 reported cases could cervical implantation be proved. These 10 plus the 1 reported by the author in 1926 and the 1 described here are the basis for the present discussion on the anatomic and clinical data of the cervical implantation of the ovum. This type of ectopic gestation is almost always associated with violent symptoms. Whether a cervical pregnancy terminates spontaneously by rupture of the extremely thinned cervical wall or by internal rupture of the gestation sac (abortion) or whether it is interrupted artificially, the leading and most alarming symptom is always the violent hemorrhage associated with it.

Murine Typhus in the Rat and in Man.—Rats were collected throughout San Antonio and tested for complement fixing antibodies for typhus. The human cases were investigated to determine the most probable source of infection. Davis and Pollard observed that the fairly good residential areas and the business districts had about 40 per cent of rats positive. The slum district had about 60 per cent of the rats positive. Human cases originated in all districts and showed a general correlation with the percentages of positive rats.

Streptomycin in Asiatic Cholera.—As Reimann and his associates have noted, cholera, when properly treated, is a disease of short duration and of low mortality. The restoration of salts and water and good medical care are the most valuable therapeutic procedures. The behavior of the disease suggests that dehydration and the depletion of salts are of far greater importance than toxemia in the causation of death. Other than a prompt reduction of the numbers of vibrios in the stools and slight shortening of the attacks, there is no evidence that streptomycin given orally or parenterally influences the disease. Strains of Vibrio comma vary greatly in their resistance to streptomycin in vitro.

Quinacrine Suppression of Malaria: Individual Failures.—Bang and his co-workers studied the efficacy of quinacrine suppression of malaria in American and Australian troops in New Guinea and Australia. The concentration of quinacrine present in the plasma of those developing malaria despite supposed suppression is compared with data from adequately suppressed troops. This comparison shows that clinical malaria develops in the presence of inadequate amounts of quinacrine. The development of malaria in a person cannot be taken as proof that he has failed to take quinacrine regularly. Variation of drug level obtained with a standard dose is so great that, granting concentration is related to protection, a small percentage would be unprotected by the standard dosage of 0.7 Gm. of quinacrine per week. Studies of the concentration of quinacrine in the plasma fail to indicate need for a dosage greater than 0.1 Gm. per day.

Contact Dermatitis from Japanese Rifles.—Hinman observed 7 cases of itching vesicular dermatitis, usually of the hands and forearms, among 150 men who had refinished the stocks of Japanese guns with scrapers and sandpaper. The lesions responded to removal of the allergen and local treatment. Since many of these rifles are in the hands of men returned from overseas, scattered cases will probably be seen throughout the country. Care should be used by individuals with known sensitivity to plant and other allergens, and that of poison oak or ivy in particular, when handling articles coated with Japanese lacquer or varnish.

Bronchiogenic Carcinoma.—Lindskog relates his experience in 100 consecutive cases of primary pulmonary cancers. There were 82 male and 18 female patients. The first symptom was usually cough, pain in the chest or a griplike cold. Sixty-five patients were inoperable when first admitted. Three refused treatment. Surgical exploration was performed on 32. Twenty of the 32 patients were found not suitable for resection. Twelve patients were submitted to surgical resection (10 pneumonectomy, 2 lobectomy), with a hospital mortality of 25 per cent. Three patients are surviving 2.5 to 5.5 years after successful resection. All had squamous cell carcinoma. They are now clinically well. One patient survives and is working 3.5 years after radiation therapy. Radiation therapy increased the average life expectancy from 5.0 months in the untreated group to 8.6 months in the group which was treated by radiation, with or without surgical exploration. This difference of 3.6 months does not have statistical significance.

Subtotal Gastrectomy for Duodenal Ulcer.—Allen and Welch think that from 10 to 15 per cent of cases of duodenal ulcer must be treated surgically. This group includes ulcer patients in varying degrees of chronicity who have developed cicatricial stenosis, those who bleed massively with each exacerbation and those who continue to have pain on the ambulatory medical regimen. The authors thought that the operation should attempt removal of the distal two thirds of the stomach and the ulcer bearing segment of the duodenum. Failures due to technical difficulties with the duodenal stump made it obvious that the risk was too great to pursue this procedure in all cases. Four different modifications which have been more successful are described. A table which classifies the results in 129 cases shows that the results were excellent in 112 cases, satisfactory in 8 and poor in 9 cases.

Late Results in Ulcerative Colitis.—Cave examined 50 of 80 patients who survived operation for ulcerative colitis. Forty were at work. The ileostomy bag has proved not very annoying. Many of the younger patients are able to play golf and baseball, some play tennis and a few even swim in the ocean. There were 3 who showed malignant changes originating in a polypus in some part of the colon. These 3 patients are still alive from three to seven years after colectomy. Another patient developed a carcinoma in the remaining rectal segment, failed to notify her physician of persistent bleeding and returned to the hospital with an inoperable lesion. She died. The fecal stream has been successfully reestablished in 2 patients by ileosigmoidostomy. Prolapse of the ileum through the stoma frequently has been a serious complication. To prevent irritation of the skin about the ileal stoma, compound tincture of benzoin, followed by generous applications of fullers' earth or a dusting powder, is generally effective. Acute ileus due to adhesions or a volvulus is not an infrequent occurrence. Sudden collapse from salt deprivation is treated with large amounts of salt orally and intravenously. There is no standard diet for all patients with ileostomy, but fruit juices and leafy vegetables should be avoided.

Streptococcic and Nonstreptococcic Diseases of the Respiratory Tract.—According to Rantz and his associates hemolytic streptococcic infection of the respiratory tract is usually of acute onset and associated with chills, headache, generalized aching and prostration. The prevailing symptom is sore throat, with tonsillar and pharyngeal exudate and redness and edema of the pharyngeal tissues. Tender anterior cervical glands are nearly always observed. Nonstreptococcic disease of the respiratory tract is typically a disorder associated with cough and hoarseness. Nasopharyngeal tissues are nearly normal. Exudate, edema and redness are minimal or absent. Tender anterior cervical glands are rarely observed. The authors think that a differentiation between streptococcic and nonstreptococcic diseases of the respiratory tract in adults may be made in the northern United States with an accuracy of approximately 70 per cent without bacteriologic study of the throat flora and in from 80 to 90 per cent if this laboratory procedure is included. The situation is probably different in the Southern states, where streptococcic disease occurs infrequently and where the atypical varieties of nonstreptococcic disease would be observed more often and differential diagnosis would be more difficult.

*Surgical Treatment of Syringobulbia and Syringopontia: Report of 2 Cases. F. J. Cramer.—p. 442.

Meningoencephalitis Following Vaccination for Herpes Zoster Ophthalmicus.—Madonick reports the occurrence of meningoencephalitis in a man aged 60 following vaccination for treatment of herpes zoster ophthalmicus. The nervous complications appeared eight days after the patient had been vaccinated. It would seem that the herpes virus was activated into a full blown meningoencephalitis by the vaccinia virus.

Surgical Treatment of Syringobulbia and Syringopontia.—Cramer reports 2 cases in which he operated on the brain stem successfully for the relief of syringobulbia and syringopontia. Syringomyelia, syringobulbia and syringopontia are topographically different expressions of the same basic pathologic process. They are due to anomalous congenital dysplasia of ectopic gliogenous cell rests within the neuraxis, and the symptoms are caused by the sequelae of the developmental maturative and degenerative processes which these undergo. In both cases the condition simulated neoplasm clinically in the progression of symptoms. In both cases the syndrome of advancing intracranial pressure was relieved. The author concludes that syringoid myelodysplasias of the brain stem are amenable to surgical intervention. Operation should be undertaken when the course is relentlessly progressive and there is advancing intracranial compression.

Ménière's Syndrome.—Atkinson brings together the evidence which supports the view that dysfunction of the capillaries is the basic fault which produces the disturbance of the labyrinthine function. Increased permeability of the capillaries explains the histologic picture. The treatments by reduction of water intake and sodium intake or by increase of potassium intake owe their beneficial effect to diminishing the amount of fluid available to seep through the abnormally permeable capillary walls. Treatment with histamine or nicotinic acid is more fundamental, since it seeks to overcome the factor which is damaging the capillary wall. The one tries to limit the leak from the reservoir by diminishing the head of water; the other attempts to repair the walls. The author thinks that Ménière's disease is not a disease per se but a syndrome. It is the syndrome of the labyrinth in paroxysmal form and can be produced by any factor which, by increasing the permeability of the capillaries forming the stria vascularis, increases the production of endolymph, thus raising intralabyrinthine pressure. Satisfactory treatment depends on determining what that factor is and eliminating it.

Penicillin in Vincent's Angina and Follicular Tonsillitis.—Hopp treated 25 patients who had Vincent's angina with penicillin sodium in gelatin capsules, 10,000 units each, one being given every two hours for ten doses. Cure was obtained in twenty-four hours. Thirty-seven patients were treated similarly for acute follicular tonsillitis, with the body temperature falling to normal in twenty-four hours and great symptomatic relief; cure was obtained in three to five days. The author considers this a preliminary report and says that further study is required to determine (*a*) the least number of doses of penicillin necessary for cure and (*b*) the smallest dose that will yield results as good as those obtained with the doses mentioned.

Necropsies on Okinawans.—The necropsies reported by Steiner were done on 150 Okinawans. There were 51 males and 99 females, and the ages of the subjects varied between 18 days and 95 years. Death was due to combat injuries in 100 cases, to noncombat (chiefly medical) causes in 36 and to a combination of war injuries and medical conditions in 14. Apart from the combat injuries these necropsies reveal differences from what would be expected in a similar series in the United States. The most striking finding was the low incidence of retrogressive and degenerative changes. Senility came late, and cardiac and skeletal muscles remained well preserved even in the aged. Arteriosclerosis also developed late or not at all, and its lethal sequels in the brain, the kidneys and the heart were never seen. Hypertensive cardiovascular-renal disease was not seen except in 1 case of the type associated with toxemia of pregnancy. Although cirrhosis of the liver was common, disease of the biliary tracts, including cholelithiasis, was not. The low incidence of malignant neoplasms also was of interest. There was a suggestion of excellent endocrine balance in the absence or the low incidence of hirsutism in women, pathologic obesity, thyroid disease, diabetes, cystic diseases of the mammary gland, fibroids and endometrial disease of the uterus, and nodular hyperplasia of the prostate and the adrenal glands. There was no disease of the stomach except ulcers; these were acute and may have been related to the *psychosomatic stress incidental to the bombing and invasion.* There were no scars of healed peptic ulcers. The most important medical problems apart from the combat injuries were the infectious diseases. Tuberculosis, dysentery, pneumonia and tetanus took heavy tolls. Filariasis appeared to be common but was of a benign form. The incidence of intestinal helminthic infections was high, but here again the clinical effects were negligible.

Atherosclerosis in Dogs.—Arterial lesions similar in distribution and morphologic character to those seen in human atherosclerosis and arteriosclerosis were found in dogs following prolonged hypercholesteremia. The high serum cholesterol levels were produced by feeding 10 Gm. of cholesterol in 40 cc. of cottonseed oil daily to dogs whose thyroid function was modified by administration of thiouracil. Although arteriosclerosis of man is too protean a disease to have a single cause, Steiner and

Kendall think that the results reported here justify the belief that at least in the cases in which arteriosclerosis follows hypercholesteremia the disease is similar to that produced experimentally in animals.

Penicillin in Intestinal Obstruction.—Blain and his associates present an account of 5 dogs in which resection of a strangulated ileac obstruction was performed at a period twice as long after the production of the strangulation as any control dog not treated with penicillin lived. Four of these resections were completely successful, and the dogs were cured. Blain recommends therapy with massive doses of penicillin in all cases of acute intestinal obstruction in which strangulation is believed to be present or in which strangulation cannot be ruled out. This should be an adjunct to and not a substitute for early operation on such obstructions.

Acute Fulminating Ulcerative Colitis with Peritonitis.—A woman aged 43, hospitalized in profound shock, had had diarrhea for four weeks. Daily treatments included repeated attempts to pass a Miller-Abbott tube to relieve distention and the administration of plasma, blood and solutions containing salt and sugar. Sodium sulfadiazine was given parenterally. Improvement continued for three days, with a slight drop in the pulse rate, stabilization of the blood pressure, clearing of the mental state and decrease in discomfort. On the fourth hospital day the patient began to pass large amounts of bright red blood by rectum. She developed profound peripheral collapse, which was not remedied by repeated transfusions; she died on the fifth day. Necropsy revealed acute ulcerative colitis with extensive necrosis resulting in the disappearance of the ventral (antimesenteric) half of the entire colon from the ileocecal valve to the sigmoid. The remaining wall of the large bowel appeared as an open trough with severe cellulitis and erosion into the submucosa and muscularis. Anal excoriations and a rectovaginal fistula were noted. A table summarizes the salient features of 5 acute cases together with those of the present one. Chisholm emphasizes that this condition probably differs etiologically from the "fulminating" form of thromboulcerative colitis described by Bargen. He regards well timed surgical intervention in conjunction with general supportive therapy as the best treatment.

Quinacrine Dermatitis and Aplastic Anemia.—Commenting on the large number of soldiers who developed skin eruptions during treatment with quinacrine, Drake and Moon show that the cutaneous reactions to quinacrine may be divided into three groups: (1) the lichenoid, which is the type primarily to be considered in this report, (2) the eczematoid and (3) the generalized exudative and exfoliative type. Treatment should consist in cessation of administration of quinacrine, general supportive care and dermatologic care along accepted lines. X-ray therapy was of no benefit, and heavy metals and arsenic cannot be recommended. Aplastic anemia was the most common cause of the death of patients with skin lesions due to quinacrine. Aplastic anemia was present in 9 cases of quinacrine dermatitis coming to necropsy.

Bilateral Frontal Lobe Leukotomy in Mental Disease.—McKenzie and Proctor, after briefly reviewing the history and physiologic basis for frontal lobe leukotomy, discuss the operative technic and the selection of patients. They performed the operation on 27 patients in whom all other recognized psychiatric therapies were employed to no avail. A common clinical finding was that of fear, agitation or impulsive behavior. Approximately 85 per cent of the cases have shown improvement ranging from improved nursing problems to complete recoveries. Thirteen of 27 patients who were previously considered to be hopelessly mentally ill have been returned to community life. The only complication observed is that of a mild hypersexuality in 25 per cent of the cases.

Aversion Treatment of Alcoholism.—The conditioned reflex treatment depends on an aversion or distaste for alcoholic beverages by virtue of their association during treatment with drugs—emetine, pilocarpine and ephedrine—which make the patient sick. The repeated association of the two stimuli alcohol and drugs under appropriate circumstances will result finally in the ability of the conditioned stimulus (liquor) to produce the symptom complex formerly brought about by the unconditional stimulus (drugs). The conditioned reflex treatment of selected patients produces results in from 40 to 80 per cent of them. Shanahan and Hornick report that of 24 patients thus treated 70 per cent are abstinent, 17 per cent are improved and 13 per cent are unimproved. The conditioned reflex treatment is not a general panacea for alcoholism, since the great majority of those afflicted fail to recognize the true nature of their disorder and decline definite therapy.

Family Physician—Reminiscence. J. B. Maple.—p. 499.

Chronic Brucellosis.—According to Moss the most constant manifestations of chronic brucellosis are chronic fatigue and exhaustion, arthralgia and myalgia, occasional vague gastrointestinal symptoms, mental depression and apprehension, with or without chronic pyrexia, and a complete lack of physical findings. An epidemiologic history of contact is necessary. The acute phase of the disease may never have existed, and serum agglutination titers are more frequently negative than positive. Blood cultures may well be expected to be negative in the chronic phase of the disease. Opsonic-phagocytic indexes are ordinarily unobtainable. The skin test is the most reliable and the most convenient test for the general practitioner. The author uses the skin test for brucellosis in all cases presenting a history of chronic fatigue and exhaustion, arthralgia and myalgia, associated with an absence of physical findings, with or without chronic pyrexia. More than four hundred skin tests have been given. About 19 per cent have been positive, but treatment is instituted only if the symptomatology warrants it. Vaccine therapy has given good to excellent results in 90 per cent of 74 patients with chronic brucellosis.

*Review of Studies on Immunity to Vivax Malaria. M. F. Boyd.—p. 437.
The Doctor Treats the Patient. Lauren H. Smith.—p. 446.

Immunity to Vivax Malaria.—According to Boyd the outcome of the inoculation of an institutionalized neurosyphilitic patient usually cannot be predicted. This uncertainty is due to the circumstance that the mental deterioration of the patients rarely permits them to give an accurate history of prior experience with this disease. Their response to inoculation with Plasmodium vivax permits of their classification in four categories: (1) inoculation resulting in a take, (*a*) an attack of three weeks or longer, (*b*) a short attack lasting from one day to two weeks, (*c*) without a clinical attack and (2) inoculation not resulting in a take. An interpretation of the significance of these results is permitted from the homologous or heterologous reinoculation of patients. Since infections of the character of 1 *a* have never been observed subsequent to reinoculation, it is inferred that patients with attacks of three weeks or more in duration were previously completely susceptible. Results like 1 *b* may follow either heterologous or homologous reinoculations and in the latter case indicate that immunity is incomplete. Following homologous reinoculation, results like 1 *c* or 2 may be secured. The latter indicates a very effective immunity or refractory condition. It is readily made evident by reinoculation with demonstrably infectious material that convalescents from vivax malaria have a distinct and at times potent immunity to the homologous parasites.

Gelsemium in Preparalytic Poliomyelitis.—Holman used gelsemium (yellow jasmine root) for its antispasmodic action in the treatment of 60 patients with acute anterior poliomyelitis. Since less than 7 per cent of those treated had clinical paralysis, it is concluded that the drug is effective if diagnosis can be made early and treatment begun before there is permanent damage to the nervous system. The margin between its therapeutic and toxic concentration is reported to be narrow.

Differentiation of Proteus and Paracolon Cultures.—Christensen describes a urea medium which eliminates the necessity of an organism's utilizing urea ammonia as a sole source of nitrogen and which is therefore capable of demonstrating urease activity in organisms somewhat more fastidious in their nitrogen requirements. The medium shows that, in addition to Proteus, paracolon Aerobacter and paracolon intermediates are definitely urease positive. Paracolon Escherichia as well as Salmonella and Shigella species are urease negative. The medium is recommended as an aid in routine enteric bacteriology.

Water Test in Diagnosis of Addison's Disease.—Levy and his associates report the results of the water test at the Mayo Clinic between 1941 and 1945. The first procedure is based on the inability of patients with adrenal cortical insufficiency to excrete orally ingested water at the normal rate. The second procedure employs a formula which takes into account the volume of excreted urine and the clearances of urea and chloride from the blood. The delayed excretion of water, such as usually occurs in Addison's disease, will not by itself establish the diagnosis of the disease. False positive responses to the first procedure may occur in many seemingly unrelated clinical conditions. Such false positive responses usually indicate the presence of organic illness not necessarily Addison's disease. Normal diuresis following ingestion of water (false negative result of test) occurs relatively infrequently in cases of Addison's disease, having been found 9 times in 74 cases. When such a false negative result is encountered it is difficult to establish Addison's disease by any other diagnostic procedure. In the presence of adequate clinical evidence and failure of normal diuresis, the diagnosis of Addison's disease can usually, but not invariably, be established by the second procedure. This one occasionally gives false positive results, but these occur with much less frequency than does delayed diuresis. False negative results occur even more rarely, and when they do it is again difficult to establish the diagnosis of Addison's disease by other laboratory criteria. Administration of sodium chloride, desoxycorticosterone acetate or adrenal cortex extract in amounts commonly employed in the treatment of Addison's disease did not seem in a limited number of cases to rectify the abnormal factors that account for the production of abnormal water tests. Patients having Addison's disease apparently lack the capacity to excrete at normal rates both orally ingested water and water given intravenously as 5 per cent solution of dextrose. From this it is concluded that, even if ingested water should be absorbed at a normal rate, its rate of excretion would be delayed.

Clinical Uses of 2,3-Dimercaptopropanol (BAL).—Eagle and his associates say that, in the search for compounds capable of acting as decontaminants or antidotes for toxic arsenicals, it was reasoned that simple dithiol compounds might form relatively stable ring compounds with lewisite or other trivalent arsenicals and might consequently compete effectively with the dithiol proteins in the tissues. A large series of dithiol compounds was prepared and tested and 1 in particular, the 2,3-dimercaptopropanol, recommended itself as a local decontaminant in combating the arsenical blister gases. This compound is generally known as "BAL" (British antilewisite).

BAL in Acute Mercury Poisoning.—Longcope and his co-workers present observations made on 23 patients who were admitted to the Johns Hopkins Hospital with a history of having swallowed from 0.5 to 20 Gm. of mercury bichloride and who were treated with BAL. All except 1, who was treated initially with small amounts of BAL, recovered.

Changes in Blood Coagulation Following Coronary Thrombosis.—Ogura and his associates studied 27 cases of acute coronary thrombosis to find evidence of accelerated blood coagulation. In more than three fourths of the cases an acceleration as measured by the Waugh-Ruddick test occurred usually by the second or third day, lasting to about the seventeenth day. Of 16 controls, 9 being in various stages of heart failure, none showed acceleration to the degree seen in coronary thrombosis. Such complications as new coronary thrombosis or extension of the original thrombus or pulmonary infarction developed in 5 patients when acceleration was present, suggesting that this factor may be contributory. The findings suggest also that the first attack is not initiated by accelerated coagulability of the blood and that after the fourth week the clotting mechanism is indistinguishable from normal.

Nasal Carriers of Beta Hemolytic Streptococci.—One hundred and nine ambulatory nasal carriers of group A hemolytic streptococci in two army camps have been studied from the standpoint of the antistreptolysin response of the blood serum and in most instances of signs and symptoms of respiratory infection. Contact carriers and probable contact carriers among this group were uncommon, comprising less than 5 per cent of the total. Missed cases, probable missed cases and "possible missed cases" accounted for 67.6 per cent of carriers in one camp and 94 3 per cent in the other. In one camp 24 3 per cent were not classifiable by the criteria laid down, though it seems likely that most of these were probably missed cases also.

Pleuropneumonia-like Organisms.—Wallerstein and his associates carried out a series of agglutinations on the serums of 102 patients for titers against one strain of pleuropneumonia-like organisms. Four significant titers were observed in patients each of whom had various combinations of colitis, arthritis, conjunctivitis, urethritis or cervicitis and skin lesions. Two of these 4 had the characteristic triad of arthritis, conjunctivitis and urethritis that justified a tentative diagnosis of Reiter's syndrome. No positive titers were obtained in patients with uncomplicated arthritis or colitis. The possible relationship of pleuropneumonia-like organisms to rheumatoid arthritis, chronic ulcerative colitis and Reiter's syndrome is discussed.

Surgically Removed Foreign Body Embolus.—Welin and his associates report the surgical removal of a foreign body from the left lung of a man aged 21. While working in the forest a splinter from an iron wedge struck him and entered the left groin He was operated on for a lesion of the femoral vein and later for arteriovenous aneurysm Since then he has had pain and swelling of the left leg One year after the accident the patient caught cold and had a cough followed by an acute attack of ague and a stitch in the left side of the back. The diagnosis of foreign body embolism in the pulmonary artery was made by combining ordinary x-ray examination with bronchoscopy. The patient emphasized that there was nothing to indicate inhalation; he had not received any direct injury on the penetration of the splinter, so that the only possible way in which the foreign body could have entered was through the femoral vein of the groin and by the blood stream into the pulmonary artery. The foreign body was extracted by thoracotomy plus arteriotomy followed by vascular suture

Intrathoracic Gastric Cyst.—Dickson and his co-workers report the surgical removal of a congenital gastric cyst from the mediastinum of a girl aged 10 The patient gave a long history of repeated "pneumonic" attacks X-ray examination revealed a massive atelectasis of the lower lobe of the left lung and a portion of the upper lobe. There was a shift of the heart and mediastinum to the left side On bronchoscopy a large amount of purulent secretion was aspirated from the left side. Surgical intervention revealed a large cystic mass with partial extension below the diaphragm

Penicillin in Tuberculosis and Mixed Infection Empyema.—According to Callahan and Sanderson, all tuberculous persons in whom empyema develops should be studied for infections with secondary pyogenic organisms as well as for tubercle bacilli When secondary pyogenic organisms are found the patient should have the benefit of intrapleural penicillin therapy. Whether it should be combined with intramuscular penicillin treatment should depend on the individual case It is a mistake to expect benefit from penicillin therapy in cases of uncomplicated tuberculous empyema.

Bacterial Endocarditis of Tricuspid Valve.—Karotkin and Marcuse say that the clinical picture of bacterial endocarditis of the left chambers of the heart is well known, while the clinical picture of bacterial endocarditis involving the right chambers is less well known. Early diagnosis of the involvement of the right side is difficult because signs of organic heart disease are often lacking, especially when the tricuspid valve is the only one involved. The blood culture usually remains negative, and systemic embolism fails to appear unless and until tissue breakdown occurs in the lungs. Cases in which the right and left heart chambers are both involved are more common than those in which the right side alone is involved. One should therefore always suspect the coexistence of a right sided lesion *in a patient with known left sided bacterial endocarditis.* Likewise, when a left sided bacterial endocarditis is suspected by bacteremia and evidence of systemic embolism fails to appear, one should suspect an isolated lesion on one of the right sided valves. Three different modes of pathogenesis arise for consideration in case of bacterial endocarditis: (1) bacterial involvement of a valve previously damaged by rheumatic endocarditis, congenital defect or trauma, (2) bacterial endocarditis as a sequel of pneumonia and (3) bacterial endocarditis as part of generalized septicemia. The findings in bacterial endocarditis of the bicuspid valve correspond with the rare occurrence of isolated rheumatic lesions on the tricuspid and with the fact that the valve is more likely to be implicated when the virulence of the organism is high. The clinical picture may become atypical early in the course of the disease because of impaired efficacy of the lung filter due to the presence of pulmonary lesions.

Spontaneous Rupture of Kidney.—According to Beard, spontaneous rupture occurs in a kidney already damaged by disease in which there is no history of trauma. Hydronephrosis, pyelonephritis, pyonephrosis, tuberculosis, abscess, infarct, nephritis, tumor, aneurysm and renal calculus have been the predisposing causes in the reported cases. The tear may be in the renal pelvis or in the parenchyma, the former of which leads to bleeding into the renal fossa while the latter leads to extravasation of urine within the perirenal fascia or peritoneum. In a kidney thus weakened by disease the slightest indirect trauma may rupture the organ. The author reports a case in which the rupture occurred while the patient was in bed. The condition can be diagnosed by careful history, physical examination and pyelography. Spontaneous rupture of the kidney is a surgical emergency, and prompt intervention is often a life saving measure. The case reported illustrates the prompt response to surgery with the postoperative administration of streptomycin in the presence of Proteus bacillus infection.

Curare to Differentiate Muscle Spasm from Organic Changes.—Jones and his associates experimented with curare in the differentiation of organic from functional factors in limitation of passive motion at joints. Seventeen patients showing limitation of passive motion at joints were given curare intravenously in the form of "intocostrin." Each patient received morphine sulfate $\frac{1}{8}$ grain (8 mg.) and atropine sulfate $\frac{1}{200}$ grain (0.3 mg.) subcutaneously thirty minutes before the administration of curare. "Intocostrin" was administered in the operating room by a trained anesthetist, with tracheal tube, respirator and neostigmine to counteract the curare effect close at hand. The "intocostrin" was injected slowly into the antecubital vein. Each patient was given the amount of curare that rendered him unable to lift his head from the table and produced weakness of the hand grip and of the thigh muscles. Some patients were given an initial dose of 50 mg. while others received 20 mg. of "intocostrin." Additional curare was injected at intervals of two to four minutes until the desired effect was produced. The largest dose given was 100 mg. Eight cases showed increases in range of motion while under the curare effect, while 9 cases showed no essential change. The test should be of practical importance in establishing the correct approach to therapy. In 5 of 7 fracture cases which showed increase in range of motion from curare the improvement was retained in full or in part, which suggests the possibility of using curare as an adjunct to treatment of such cases. Curare can relieve joint pain by relaxation of muscle spasm.

Is Overspecialization a Threat? C. A. Dawson.—p. 1045.

Erysipeloid.—Erysipeloid of Rosenbach is a disease in man which is caused by Erysipelothrix rhusiopathiae, the organism of swine erysipelas. The first 4 of the 5 cases presented by Macaulay are typical of the clinical picture of erysipeloid. Three cases occurred in butchers and serve to reemphasize the occupational nature of the disease. The first 2 cases demonstrate the apparent inability of sulfonamides to control erysipeloid. The second case later responded promptly to penicillin. The third and fourth cases showed rapid subsidence of symptoms with penicillin as the sole therapeutic agent. The author comments on the recent increase in cases of erysipeloid and thinks that more can be expected. Penicillin is the best treatment.

Specific and Nonspecific Reactions to Influenza B Infection.—Burnet and Stone show that convalescent serums taken after an influenza B infection show specific and nonspecific types of response. In children and adolescents the commonest type is specific, showing a much higher titer both by hemagglutination and by allantoic methods against a homologous strain than against the classic strain Lee. Most adults show equivalent titers against the two types of virus, but a proportion of specific responses is found. Influenza B virus strains isolated in 1943 or 1945 form a fairly homogeneous group when tested with specific human serums and differ sharply from Lee. The significance of these findings in relation to immunization against influenza B is briefly discussed.

Receptivity of Cervical Mucus to Spermatozoa.—According to Barton and Wiesner, semen and cervical mucus are virtually immiscible. Fecundation depends on the ability of the sperms to penetrate the interface between mucus and semen. In many sterile women the mucus does not admit or sustain spermatozoa. The nonsurgical treatment of cervical dysfunction is briefly surveyed.

Osteomyelitis of Lumbar Spine in Adult.—A man aged 43 presented symptoms that were regarded as indicative of Pott's disease. Laboratory examinations, however, suggested a pyogenic rather than a tuberculous abscess. Aspiration of the abscess yielded pus with Staphylococcus aureus. The further development and exposure of the abscess indicated that the pus had tracked from the lumbar spine into the pelvis, along the structures, passing through the sacroiliac foramen to the gluteal region and to the front of the thigh, where pressure on the femoral vein resulted in generalized swelling of the limb. The abscess cavities were insufflated with sulfathiazole powder mixed with 100,000 units of penicillin, and a drainage tube was inserted. A transfusion of 2 pints of blood was given, and penicillin in 30,000 unit doses intramuscularly was continued four hourly. The patient recovered, so that he could walk freely without discomfort. Freeman points out that the case is of special interest because of the insidious onset, the age of the patient and the resemblance to tuberculous disease of the bone and the development of a large collection of pus in the presence of a small area of bone necrosis.

Efficacy of Insecticidal Sprays in Aircraft.—According to Garnham, routine disinfestation of aircraft is now carried out practically everywhere in the tropics. The author describes a simple test which uses mosquitoes in cages as an indicator to check the efficacy of the disinfestation of aircraft. The results suggest that the simple methods used in the disinfestation of aircraft are adequate, even for the more inaccessible parts of the machines, provided the dosage is large enough and the solutions are freshly prepared. There is one exception, however, and that is the apparent ability of mosquitoes to survive even heavy doses if protected by any sort of cloth. Although the initial excitatory effect of the insecticide may drive out mosquitoes hidden in coat sleeves and similar places, the danger remains.

Penicillin in Leptospirosis Canicola.—Baber and Stuart's patient was a boy aged 11 who had bathed in the Thames and whose disorder was diagnosed as infection with Leptospirosis canicola by the demonstration of a rising serum antibody titer to L. canicola during the course of the illness and by absorption tests with homologous and heterologous strains of leptospira. The patient was treated with 220,000 units of penicillin, and dramatic clinical improvement followed. Since this is the first case of L. canicola infection discovered in Britain, it is unfortunate that the organism was not isolated from the patient, but on serologic grounds the evidence is quite definite.

Malignant Granuloma of Nose.—In the man whose illness is described by Hargrove and his associates the main feature was a rapidly spreading ulcerative condition involving the antrum, nose and palate. The histologic picture was that of an acute granuloma with necrosis. It is impossible to decide whether the condition was due to an infection or to an unusual type of sarcomatous change.

Aspiration Type of Congenital Tuberculosis.—Pagel and Hall report the universal spread of submiliary foci throughout both lungs of a girl aged 17 days and confluent caseation in the hilar lymphatic glands. Caseous plugs abounding with acid fast bacilli were found to fill dilated bronchioli and alveolar ducts, forming "multilocular" foci resembling those obtained in primary intratracheal infection with heavy inocula and consistent with infection by coarse aspiration. A congenital origin suggests itself because of (1) the wide extent of the lesion, (2) the picture differing from the pulmonary "primary complex," (3) the extensive cellular reaction of the lung stroma, incompatible with seventeen days' duration. The wide and obviously primary involvement of the bronchial system points to infected amniotic fluid as the source and to aspiration as the mode of infection. Although clinical or pathologic data as to the condition of the mother, placenta and amniotic fluid were not available, it is reasonable to suppose that the latter was at one time infected with tubercle bacilli and aspirated.

Malignant Primary Tuberculosis of Adults.—According to Dufourt, severe and often fatal pulmonary tuberculosis resulting from primary infection in adults represents in the great majority of the cases the first and secondary stage rather than the third stage of the disease. Either the patient may have primary cavities, or the breaking down of a lymph node may lead to bronchopneumonia or to miliary or generalized tuberculosis resembling that occurring in children. Death may result within the first year or within the first months of an exacerbated second stage. Only a few patients have been observed who presented the third stage after a brief secondary stage of tuberculosis. In 1 of the author's patients the allergy was detected. This was followed by pleurisy; after an interval of six months osteitis developed in twelve ribs and was rapidly followed by dissemination of the process. A severe and prolonged infection may be responsible for malignant primary tuberculosis of adults.

*Capillary Resistance and Vitamin with Effect on Permeability. P. Galmiche.—p. 1463.

Capillary Resistance and Vitamin P.—Galmiche reports the occurrence of scurvy in a woman aged 75. The food supply of the patient was that provided by the ration card. She ate only boiled food and abstained from eating raw fruit and vegetables. Peribuccal purpura associated with severe chills was followed by generalized purpura involving the mucous membranes and the viscera. The patient's condition deteriorated in spite of intravenous administration of 1 Gm. of ascorbic acid daily for twenty days. Parenteral administration of 5 Gm. of vitamin C daily for four days was ineffective. An intravenous injection of 12 mg. of epicatechine (one of the isomers of 3,5,7,3'4' penta hydroxyphenyl benzo-gamma-pyrane) was given, and two more injections of 8 Gm. were given on the two following days. There was rapid improvement, and complete recovery resulted within a few days. The bleeding time was reduced from 14 minutes to 3 minutes, and hematuria subsided.

Cardiac Trauma Produced by Blunt Force (Commotio and Contusio Cordis). M. Kartagener.—p. 289.

Familial Incidence of Cardiac Failure.—Von Rechenberg reports the occurrence in a family of rheumatic cardiac involvement in the father, in 1 son and 1 daughter and in 1 illegitimate son of the mother. In 3 of the patients the cardiac failure was associated with acute rheumatic polyarthritis. Familial incidence of cardiac failure suggests that hereditary factors may play a part in the pathogenesis of acquired cardiac failures. These factors are (1) hereditary predisposition to diseases in which involvement of the heart is part of the disease, (2) congenital cardiac inferiority on a hereditary base and (3) local hereditary predisposition of the valves toward disease. The hereditary predisposition may, from the genetic point of view, be always the same although its manifestations may vary considerably, depending on the predominance of one or the other of the hereditary factors, on the time when this factor becomes effective and on the influence of the environment. Severe congenital defects of the heart, simple uncomplicated vitia cordis, fetal endocarditis and acquired failure of the cardiac valves may be interrelated so far as the genesis and the evolution of pathologicoanatomic events are concerned. Familial incidence of cardiac failure depends on a hereditary predisposition but does not represent a specific hereditary disease. Hereditary incidence of cardiac failure is related to congenital heart failure, rheumatism and bacterial endocarditis.

Rheumatic Cervical Perispondylitis and Cervical Syndrome.—Belart designates as cervical syndrome a clinical entity which manifests itself chiefly in paresthesias in the hands with neuralgiform pains and a leaden heaviness in the arms. Later this becomes complicated by stiffness of the neck and radiation of pain from the neck to the occiput and the shoulders. This syndrome is traced back to rheumatic perispondylitis or rheumatic inflammation of the soft tissues of the spinal column, particularly to involvement of the ligaments and to multilocular tendoperiostitis. These spread to the sympathetic nervous system centered there and cause various sympathetic disturbances. The terminal phase of the perispondylitis is spondylosis. As regards the etiology, not only the mechanism of focal infection plays a part but also the continuous spread from the tonsils. There may be a causal connection not only with spondylosis, which represents the terminal phase of perispondylitis, but also with muscular rheumatism, neuritis, neuralgia, osteoporosis of the spinal column, chronic meningitis and neurovegetative dystonia.

Carcinoma of Islands of Langerhans Without Endocrine Manifestations.—Hess was able to collect reports of 19 cases of carcinoma of the islands of Langerhans from literature. Whenever the sugar metabolism was studied in these cases hyperinsulinism was discovered, except in the thoroughly investigated case of Dubois-Ferrière. The author reports a case in which necropsy established a pancreatic carcinoma that originated in the insular tissue. In contradistinction to most other tumors of this type, this cancer had produced no insulin and had not produced hypoglycemia. This was explained by the fact that the cancer was composed exclusively of the endocrinically inactive alpha cells. This observation indicates that it is essential to differentiate between malignant insular tumors with hyperinsulinism (beta nesocytomas) and those without disturbance of the sugar metabolism (alpha nesocytomas).

*Infectious Mononucleosis in Puerperium, with Subclinical Infection of Newborn Infant. C. Trinção.—p. 146.

Infectious Mononucleosis in Puerperium.—A pregnant woman at full term developed acute urticaria without fever. Three days later she delivered a normal baby. She nursed the baby. One week after the delivery the patient presented symptoms of acute infection with fever, and tender, enlarged lymph nodes of the neck. Penicillin was not effective. The blood picture was characteristic for infectious mononucleosis. There was a leukocytosis. Nearly all lymphocytes were abnormal. The Paul-Bunnell test for infectious mononucleosis was positive for the blood serum but negative with the mother's milk. The disease subsided within twelve days. The baby was apparently normal. His blood showed the same changes as the mother's blood, with the same type of abnormality in the majority of the lymphocytes. Blood smears from 12 normal infants between 9 and 26 days old showed normal lymphocytes in all. This is the first case of subclinical infectious mononucleosis in an infant most probably acquired before birth.

Pheochromocytomas of the Adrenals.—According to Espersen and Dahl-Iversen a pheochromocytoma is a tumor caused by abnormal proliferation of mature medullary cells. The first of the 2 patients seen was a man aged 49 who had paroxysmal hypertension due to benign pheochromocytoma of the right adrenal. The epinephrine content of the blood was found to be from four to five times increased during attacks. Treatment with methyl thiouracil resulted in complete disappearance of the attacks. Good results were obtained by removal of the tumor, which weighed about 1,400 Gm. The second patient, a boy aged 10 years, had permanent hypertension due to a pheochromocytoma which operation through a left lumbar incision failed to demonstrate. The patient died six hours after the exploratory intervention. Necropsy revealed a malignant pheochromocytoma in front of the large vessels. It was connected by a small pedicle with the lower mesial angle of the left adrenal. The only effective treatment is extirpation as soon as the diagnosis has been established and the patient's condition permits. The preoperative treatment would be like that in extirpation of the adrenals. The authors think that it might be best to choose the abdominal approach in all cases of pheochromocytoma. When the tumor is large they recommend the use of Shipley's incision. The danger of shock during operation can be counteracted by adrenal cortex extract, blood transfusion and, if necessary, epinephrine.

"Dynamite Encephalosis."—Gerle reports that a man in the course of work with explosives, while doing home defense duty, once had to tie explosives together into small bundles. It was an unusually hot and humid day. The dynamite was packed in coarse paper, which had broken here and there, so that the patient now and again came into direct contact with the dynamite. He got hot and wiped the perspiration away repeatedly. About 7 p. m. the man asked for headache tablets. He was given some codeine. At 10 o'clock he suddenly became violent and had to be held by several men. On being transported to the hospital he coughed and vomited. He complained of heartburn and a severe headache. Motor agitation alternated with confusion. After five days he was discharged. There was a striking change in his behavior. His previous brightness and liveliness were gone. He was less alert, very moody, irritable and complaining. He showed amnesia for the time before his falling ill and the ride to the hospital. Headaches continued to trouble him. The headache is the cardinal symptom of glyceryl trinitrate intoxication. For about a month the patient showed lowered alertness, deficient concentration, increased fatigue, irritability and depression.

*Surgical Treatment of Tuberculous Pleural Empyema. H. F. Harbitz. —p. 1314.

Near Distance Roentgen Therapy.—Arho reports that primary healing occurred in 197 (93.3 per cent) of the 211 cases of skin cancer treated from 1938 to 1944 by Chaoul's modified method. Fourteen cases were resistant to the treatment, in 18 recurrence appeared; the unfavorable results in two thirds of these cases is ascribed to technical mistakes in treatment. In cancer of the eyelid near distance therapy seems superior to the usual roentgen and radium treatment, as the danger of irradiation cataract is reduced to a minimum. In benign skin disorders the method is as effective as other forms of irradiation. In palliative treatment of metastases from cancer of the breast and malignant melanoma it gives better results than the usual roentgen treatment, especially if the metastases extend over large areas.

Surgical Treatment of Tuberculous Pleural Empyema.—Harbitz describes 22 cases of chronic tuberculous pleural empyema treated during the last seven years. In 6 cases the pleural cavity was closed during the treatment; 16 were fistulous and drained. Radical thoracoplasty in several stages was done. The average duration of treatment was four months and three weeks. Two patients (1 with closed, 1 with fistulous empyema) died immediately, 5 (1 with closed, 4 with fistulous empyema) died later from their tuberculous disease. The surviving 15 are abacillary; 1 has a persisting fistula and amyloid degeneration, 14 are cured, and of these 13 have been working for from one and a half to seven years.

Book Notices

Harvey Cushing: A Biography. By John F. Fulton. Cloth Price, $5. Pp. 754, with illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois, 1946.

Previously to his death Dr. Harvey Cushing made a provision in his will that a sum of money be set aside to help defray the expenses of compiling an account of his life, should his wife and his literary executor feel that the publishing of his biography might be of interest or help to medical students. In the preface to his biography of Dr. Cushing Dr. John F. Fulton, who was for many years associated with him, emphasizes the intention to prepare a work which would have the medical student primarily in mind. At the same time the endeavor was made to produce a biography that would interest nonmedical readers. Thus the work, while voluminous, fails to devote much detailed attention to the technical phases of neurosurgery or to the pathology of tumors of the brain.

Fortunately for the biographer, Dr. Cushing had collected and annotated the papers related to his family for many years, he kept a diary and his case histories were likewise scrupulously prepared and preserved. Early in his career Dr. Cushing became facile in sketching, and his diary as well as his case histories were accompanied with sketches, many of which are reproduced in the book. Any one who had the privilege of meeting and talking with Dr. Harvey Cushing recognized in him an alert and sensitive mind and the spark that is characteristic of genius. Moreover, if genius is the capacity for taking infinite pains associated with hard work, that characterization even more certainly applied to Dr. Harvey Cushing.

Following a detailed introduction to the young man and to his family background liberally supplemented with quotations from letters and portions of the diary, Dr. Fulton describes the first trip abroad and the return of Cushing to Baltimore in 1896, where he became Halsted's assistant resident in surgery. It becomes clear that the young man during the period of his studies in medicine and his internship gave little indication of the greatness that was to follow. Yet at the same time, the mere keeping of the diary and the comments revealed him well above the average of medical students. We find him on several occasions in 1893 disgusted with his progress, suffering occasional headaches and at least twice contemplating suicide. Perhaps it is a mark of greatness to suffer frequently with the feeling of discontent and dissatisfaction. Even in the midst of these depressions there are gleams of humor in which he recounts some delightful anecdotes and makes a comment such as the one relative to having broken one of his molars on some boardinghouse tapioca. The five years at Johns Hopkins University influenced Cushing greatly. He derived much from his association with Halsted and no doubt began there his first interest in books, bookplates and the acquisition of a library.

In 1900 Cushing had to make one of those tremendous decisions that come to a young man—where he would go after the completion of his service with Halsted. He made the wise decision for further study rather than in favor of increased income elsewhere. The illness of Halsted gave him opportunity for a vast amount of surgical work which might not otherwise have been available to him.

Much of the rest of the life of Harvey Cushing has been described in many notices published at the time of his death, but these hardly give the intimate detail of the innumerable decisions that he had to make in matters related to surgical appointments, research and the cases in which he operated during the years of his career. His service in the first world war has been described in his own notebooks, but the letters and documents in Dr. Cushing's files provide background material and are highly instructive. One gets the picture of a genius, a veritable virtuoso who does not fit easily into any one's classification or regimentation and whom associates and others learned to respect for his special virtues and to forgive because of these special virtues for some extraordinary quirks of character. If there is any criticism to be made of this book, it is of its enormous detail, which will detract from the interest of many readers not specifically in the field of medicine. Medical readers once embarked on its text are likely to follow through page by page for the information and attitudes so clearly set forth. It might be well for the author and publisher to consider the employment of a competent biographer or writer to make from this large volume a work of perhaps 100 or 200 pages written especially for the public, which would benefit so much by knowledge of the career of Harvey Cushing. Those portions of his will pertaining to the biography and disposition of his library are cited in the appendix. They cast further light on the virtuosity of the greatest of brain surgeons.

The Care of the Aged (Geriatrics). By Malford W. Thewlis, M.D., Attending Specialist, General Medicine, United States Public Health Hospitals, New York. Fifth edition. Cloth. Price, $8. Pp. 500, with 65 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1946.

Dr. I. L. Nascher, generally recognized as the father of geriatrics, was the first man to apply the term to the study and treatment of conditions incident to old age. When he gave up private practice to enter the public welfare department of New York City, his mantle fell on his favorite pupil, Dr. Malford W. Thewlis. The first edition of Thewlis's Care of the Aged was published in 1919. The fact that the fifth edition is now off the press gives evidence that it has met a favorable reception from the medical profession. The volume has been completely revised and a number of new subjects have been included. It is divided into eight parts, on general considerations, geratology, medicolegal relations, miscellaneous geriatric problems, diseases of metabolism and endocrine disorders, infectious diseases and focal infection, systemic pathologic conditions and special topics. This edition, like its predecessors, is characterized by a common sense approach to the conditions peculiar to old age. It is so well written that reading it is a pleasure, and the pleasure is enhanced by the fact that the book contains no excess verbiage. An example of the common sense which marks the whole book is to be found in the section on logotherapy: "Logotherapy (Gk. *logos*, word; *therapia*, healing) might be defined as the therapeutic influence of words upon diseased persons. One's first impression might be that this is a form of psychotherapy which should be employed by psychologists and psychiatrists. This is not the meaning I wish to convey. On the contrary, a careful selection of words may spare the elderly patient much mental suffering, thus making it unnecessary for the psychotherapist to clean up the wreckage physicians have produced by a tyranny of words. It is obvious that severe emotional disturbances are often caused by the wrong choice of words." Geriatrics is becoming more and more a household word. Dr. Thewlis's book can be recommended to all who want to learn more about the subject.

Illustrations of Regional Anatomy. By E. B. Jamieson, M.D. Section I: Central Nervous System; Section II: Head and Neck; Section III: Abdomen; Section IV: Pelvis; Section V: Thorax; Section VI: Upper Limb; Section VII: Lower Limb. Sixth edition. Paper. Loose-leaf. Price, 12s ; 15s ; 10s ; 8s. 6d.; 7s. 6d ; 10s.; 12s. 51 plates; 64 plates; 44 plates; 35 plates; 32 plates; 42 plates; 52 plates. E. & S. Livingstone, 16 & 17 Teviot Place, Edinburgh 1, 1946.

These little volumes, one each for the central nervous system, head and neck, abdomen, pelvis, thorax, arm and leg, consist of a series of 6 by 8 inch plates bound in such a way that the sheets are removable for convenience in dissecting. They are printed in color on only one side of fairly heavy coated paper. There is no text, and only the briefest of legends appear beneath the pictures. The plates are completely and clearly labeled, and color is used unsparingly to differentiate structures. The unique character and value of the work lies in the original and lucid presentation of gross anatomy in a manner that can be easily comprehended by medical students. Dr. Jamieson states in the preface that the first edition, which appeared in 1934, was an outgrowth of the blackboard diagrams which he used in teaching his classes at the University of Edinburgh. One can well believe it, because successive revisions and additions have not changed the author's approach to his subject. The characteristic feature of the plates is still their simple and highly graphic character. Despite (or perhaps on account of) Dr. Jamieson's diagrammatic conceptions and bright colors, one somehow manages to get a clearer architectonic idea of the human body in much less time from these illustrations than from a more lengthy perusal of the standard textbooks of anatomy. From an esthetic standpoint or as a literal transcription of the appearance of anatomy the plates do not rate overly high. However, as illustrations, in the pure sense of the word, they are excellent. It is obvious that author and artists were not inhibited by precedent or current styles in anatomic drawing but knew exactly what they wanted to do and did it. A first impression of the plates is the extensive use of color. For instance, all pictures of bone show the articular surfaces in uniform purple. Tendons, ligaments and fascia are indicated by a bright green. One may wish that the colors, which are sometimes a bit violent, were a little more restrained, but undoubtedly they achieve the purpose the author had in mind. There are no subtleties in the plates nor is there any question about what they are meant to convey. Anatomists may find that the labeling on the plates, while always explicit, occasionally departs from the terminology used in this country. Gynecologists, who make a point of such things, may not agree with Dr. Jamieson on the large size of the perineal body as shown in the sectional views of the female pelvis. These are minor points, however, and have little weight against the overall high teaching value of the illustrations.

Thromboses artérielles: Physiologie pathologique et traitement chirurgical. Par René Leriche, professeur au Collège de France, avec la collaboration d'Ivan Bertrand, directeur de l'Institut de neurobiologie à la Salpêtrière. Paper. Price, 600 francs. Pp. 537, with 59 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^{e}, 1946.

The remarkable intellectual resilience of the French, whose literary output is now gradually emerging after years of nightmare, is well documented in this monograph on arterial thrombosis. Leriche has written a true functional pathology of the vascular system restating and broadening his many pioneer views in the form of lectures presented at the Collège de France in 1944. In the preface he expresses regret for not documenting more of his recent views by animal experimentation; this was, however, obviously impossible during the German occupation. The monograph consists of a large number of clinical observations discussed in chapters on traumatic thrombosis, thromboangiitis, vascular sclerosis, coronary thrombosis and many other syndromes, which the author discusses from both the organic and the functional point of view. Leriche has stimulated more than any other man a phenomenal development of vascular surgery in the last twenty years. In the development of this field he has thrown out a multitude of ideas or novel conceptions; some of these have become accepted, are experimentally and clinically proved and have greatly enriched our tools of therapy. Others were erroneous, required modification or have gradually been eliminated. It is the typically French genius of Leriche to advance a subject on the basis of his clinical observations, deductions and analogies, which are so frequently frowned on by the sober research worker whose "feet are on the ground." While much material in this monograph sounds far from convincing and while much work will have to be done to document or disprove many of the statements, such work should prove an intellectual stimulus to those interested in vascular surgery and its advancing frontiers.

Body Mechanics in Nursing Arts. By Bernice Fash, B.P.E., B.S. Cloth. Price, $2.75. Pp. 130, with illustrations. McGraw-Hill Book Company, Inc., 330 West 42d St., New York 18, 1946.

This book is well set up and freely illustrated. The illustrations are well done as drawings and show considerable thought. Well controlled imagination has been used in the development of both the text and the illustrative drawings. As a teaching textbook its brevity and simplicity are good. As read by the person already well educated and well versed in nursing it would seem that a good share of the material was unnecessary. Many of the situations of bad posture described and their good postural alternates occur so automatically to one well acquainted with nursing and body posture that at first it seems strange to include them. The real worth of the book lies in the ability of the author to understand the student nurse's mind, get back to early essentials and realize that what perhaps seems obvious to the physician is an unexplored field to the student. The descriptions of methods of handling patients with greatest economy of effort and least danger of strain are really excellent.

X-Rays and Radium in the Treatment of Diseases of the Skin. By George M. MacKee, M.D., Professor of Clinical Dermatology and Director of Department of Dermatology (Skin and Cancer Unit) New York Post-Graduate Medical School and Hospital, Columbia University, New York, and Anthony C. Cipollaro, M.D., Assistant Professor of Dermatology and Assistant Director of Department of Dermatology (Skin and Cancer Unit) New York Post-Graduate Medical School and Hospital, Columbia University. Contributor: Hamilton Montgomery, M.D., Associate Professor of Dermatology, Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota, Rochester, Minnesota. Fourth edition. Cloth. Price, $10. Pp. 668, with 321 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1946.

This edition of MacKee's book is in every way an excellent and authoritative presentation of the subject of therapy of cutaneous diseases by x-rays and radium. It is shorter than its predecessors by some two hundred pages—always a welcome improvement—and there is better unity of organization of material in this edition than in the previous ones. This edition was written with but one collaborator, Dr. Cipollaro, and one contributor, Dr. Hamilton Montgomery, who wrote the complete and excellently illustrated chapter on pathologic histology of radiodermatitis. The book covers every phase of the subject from a historical introduction to a consideration of medicolegal aspects of x-ray and radium therapy. The chapters dealing with the fundamentals, the structure of matter, the nature of radiation, dosage, technic, physics, filtration, apparatus, protection, idiosyncrasy and biologic and biochemical effects of radiation are written with a clarity that makes a complicated subject interesting and easily understood. The material is amply illustrated. One half of the book is devoted to the treatment of various skin diseases from acne to zoster. This section is particularly practical, for it gives proper emphasis to the more important diseases. Actual dosages in roentgens and technical details with regard to filtration and treatment intervals are furnished to guide the practitioner. The undertone of conservatism in this section reflects interestingly the progress of dermatology in the past thirty years. Chemotherapy for some diseases and a better comprehension of the causation of others have replaced radiation therapy in many instances and, as the authors state in the preface, it is possible that radiation therapy will be employed even less frequently in the future. Nevertheless radiation therapy is still a most important modality and there may be many who will disagree with the authors' too conservative views. The book accurately reflects our present knowledge of radiation therapy; it is thoroughly up to date, complete, practical, well organized, fully indexed and excellently illustrated. It is recommended as a useful guide for any physician who employs x-ray and radium therapy for diseases of the skin.

What You Don't Know May Hurt You! By J. A. Rudolph, M.D., and Howard N. Rose, B.A. Cloth. Price, $1.50. Pp. 138, with illustrations. Dorrance & Company, 5th & Chestnut Sts., Philadelphia 6, 1946.

This small book is packed full of brief case reports illustrating various forms of allergy. It contains innumerable examples of possible allergies; possibly it contains so many that the point of the illustrations may become lost. Explanatory material is rather limited in quantity and elementary in type and is almost lost among the numerous illustrative case histories. In general, however, it should be useful to suggest possibilities for the cause of allergy and as a source of suggestions for possible approaches to treatment. Scientifically it is sound. Its brevity and its low price should make it a popular book among allergic patients and their long-suffering families.

Some Properties and Applications of D.D.T. Great Britain. Ministry of Supply, Chemical Defence Research Department. Paper. Price, 15 cents; 6d. Pp. 34. British Information Services, 30 Rockefeller Plaza, New York 20; His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1946.

This brief monograph summarizes much of the information now available concerning the chemistry, toxicity and uses of DDT. It has been compiled from published literature and from reports of work carried on within the United Kingdom and elsewhere. The monograph is not offered as a complete review of the subject but will provide for the average reader a useful guide for information on the physical and chemical properties of DDT, toxicity, formulas, means of dispersal and effectiveness.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PENICILLIN BLOOD LEVELS

To the Editor:—What is the duration of effective blood levels of penicillin when 200,000 units is thoroughly emulsified with Emulgen (Lakeside) or Pendil (Endo). What dosage is recommended in severe infections? What is the average duration of effective blood levels of 300,000 units of penicillin in oil and wax? J. W. Mehaffey, M.D., Birmingham, Ala.

ANSWER.—It has been demonstrated by Romansky and others that single injections of 300,000 units in peanut oil and beeswax will give maximum levels in 75 to 80 per cent of cases of 0.1 unit per cubic centimeter for a period of twelve hours or longer. As far as is known, this is the only method that has been developed that delays the absorption of penicillin local deposits in muscles. The studies that have been made with lanolin and cholesterol-like substances such as Pendil and Emulgen have been so infrequent that there is not good evidence that these substances delay absorption of penicillin.

A careful search of the literature does not disclose information concerning penicillin levels in the blood or effectiveness in diseases other than gonorrhea when penicillin is injected in these water and oil emulsions. In the curves that have been published showing the levels after injection of penicillin in water and oil emulsion there is little evidence that the absorption is delayed and certainly the levels in the blood decrease rapidly after the first hour.

DIARRHEA AND TRICHOMONAS HOMINIS

To the Editor:—A woman aged 60, otherwise in good health, has had diarrhea of four months' duration. Several stool specimens, checked by a reliable pathologist, have been found to contain Trichomonas organisms. The patient lives on a farm, does some milking and helps care for farm animals. She has never had Trichomonas vaginitis. Please discuss the diagnosis and treatment. Antony Parsons, M.D., Valley, Neb.

ANSWER.—Trichomonas hominis is an intestinal flagellate which usually inhabits the lower part of the ileum and the cecum, where it is sometimes found in abundance. The organism is seldom seen in formed stools but is not infrequently present in diarrheal states, such as bacillary and amebic dysentery, as the fluid consistency of the stools in these conditions forms an excellent medium for the growth of the parasite. Since Trichomonas hominis is almost invariably found only in diarrheal states, some observers have considered the parasite an etiologic agent of diarrhea. Competent investigators, however, have observed little experimental or clinical evidence to support the claim that the organism, per se, is capable of initiating diarrhea.

According to Craig and Faust an animal reservoir of Trichomonas hominis is not known; birds, reptiles and fish harbor species belonging to the genus and some species are found in cattle, dogs, cats, rats and other animals.

In a determination of the etiologic factor or factors of the diarrhea of the patient in question, the following is suggested:

A complete physical examination should be performed, including vaginal examination and search for Trichomonas vaginalis. Routine studies of the blood and urine and x-ray examination of the stomach, colon and small intestine are indicated, as neoplasms of the gastrointestinal tract, regional enteritis and inflammatory lesions of the colon frequently are associated with diarrhea as a presenting symptom and may be disclosed only by x-ray. Proctosigmoidoscopy is of value in determining the presence of rectal disease and in differentiating various rectal lesions when present. Stool cultures and warm stool examinations are of value in demonstrating significant intestinal pathogens. If the stools are bulky or frothy, quantitative fecal fat determination may disclose steatorrhea. A basal metabolic rate determination may disclose a masked hyperthyroidism which may manifest itself by diarrhea. If these procedures fail to reveal any significant cause for the diarrhea, careful investigation of the patient's emotional problems, her fears and anxieties, should be determined, since tension and anxiety states not infrequently are manifested by gastrointestinal symptoms, including diarrhea.

A low residue bland diet may be instituted as trial therapy in conjunction with sedation such as phenobarbital ½ grain (30 mg.) and belladonna ⅛ grain (8 mg.) after meals and at bedtime. Added hours of rest are often of value. If no improvement is obtained after several weeks to a month with this regimen, repetition of the diagnostic procedures may be desirable, as a lesion sometimes not evident at a first examination may be disclosed later.

POSSIBLE LATE MUSTARD GAS KERATITIS

To the Editor:—In World War I a Canadian field gun received a direct hit from an enemy gas shell, sending most of its crew to the hospital with mustard gas burns. A new gun with a fresh crew was immediately wheeled into the same pit and many of these men also developed mustard gas vapor irritation. One soldier had swelling of the eyelids and an irritation of the scalp, which disappeared in a few weeks. In 1937 this man developed a right corneal ulcer, which did not entirely heal for several months, although he was not totally incapacitated during this time. The cornea remained cloudy with the vision reduced to about 20/100. In May 1946 there was a recurrence, and in June 1946 a 5 mm. ulcer was noted with surrounding corneal opacity and conjunctival and deep ciliary congestion. The pupil was free. Useful vision was not present. Although there was pain this was not as severe as expected. After treatment with atropine and heat for three weeks the ulcer healed almost entirely, but the cornea showed diffuse opacity and vascularization. There were residual photophobia, redness and pain. The possibility of a delayed mustard gas vapor burn was considered. Please discuss the etiology and treatment of this condition.

H. H. Sharp, M.D., Sussex, N. B., Canada.

ANSWER.—It is possible that the patient described in the query has recurrent corneal ulcers as a result of mustard gas burns acquired in World War I. However, a definite diagnosis cannot be made from the description given. Late mustard gas keratitis has been described by Duke-Elder in his Text Book of Ophthalmology and also recently by Mann and Pullinger. The characteristic picture of this condition is intense vascularization by new blood vessels into the cornea, springing from dilated and fusiform conjunctival loops, a tendency for the sclera to invade the cornea in places, lack of corneal sensitivity in the affected area, cholesterol crystals, fatty degeneration and what Mann calls "silkiness," defined as a dappling and fine short lines. The treatment is an unhappy one. Contact glasses offer the best prospect of relief from discomfort and breakdown of the cornea. The cholesterol crystals should be picked out of the cornea, as smooth a surface as possible being left. Obliteration of the limbal vessels by repeated cauterization sometimes helps.

TOXICITY OF METHYLENE DICHLORIDE AND METHYL CHLORIDE

To the Editor:—A patient has a contact dermatitis due to a refrigerant agent, methylene and methyl chloride. His friends state that all workers with this substance eventually have heart and kidney trouble. Please discuss the effects of these compounds.

C. C. Mansell, M.D., Lubbock, Texas.

ANSWER.—Neither methylene dichloride nor methyl chloride is important as a source of contact dermatitis. At the present time methylene dichloride is widely sponsored as the hydrocarbon of choice in hand metal cleaning because of its relatively low toxic and skin irritation properties. The chief objection is its skin chilling action, its boiling point being near 40 C. Likewise systemic damage is of low prospect. This is reflected in the fact that it has enjoyed limited use as a general anesthetic. Its narcotic action is much less (two and one-half times) than that of chloroform, but it produces an alarming excitatory period. In the concentration requisite to anesthesia prompt cyanosis, dyspnea, dilated pupils and tachycardia may occur. In animals high concentrations induce renal and hepatic damage.

The consensus as to industrial usage is that methylene dichloride (dichloromethane) is comparatively innocuous except from gross acute exposures. Three hundred parts per million may be tolerated for prolonged periods—this by contrast with carbon tetrachloride with its upper limit of safety near 50 parts per million.

Methyl chloride provides a greater risk. Apart from its acute narcotic action and danger from local freezing under some circumstances, methyl chloride is dangerous when taken into the body, owing to the fact that it readily decomposes with the formation of methyl alcohol (methanol, wood alcohol). Every gram of methyl chloride taken into the body provides 0.63 Gm. of methyl alcohol. Thus methyl chloride represents a potential cumulative poison as well as an acute narcotic. Numerous deaths have followed gross exposures in connection with refrigeration, chiefly from breaks in lines of multiunit systems. Such deaths were so prompt as to preclude any likely methyl alcohol action. Notwithstanding well recognized dangers from methyl chloride, as a practical danger it falls well below carbon tetrachloride. Regular exposure to 200 parts per million is probably tolerable.

PERIODIC SWELLING OF BREAST IN MEN

To the Editor:—What is the cause and treatment of unilateral periodic swelling of the breast of man? There is a definite visible swelling which occurs in the same breast every four to eight weeks in a man aged 46. A tumor is not palpable and there is no discharge of any kind from the nipple, spontaneously or on pressure. M.D., New York.

ANSWER.—The periodic swelling of the breast in the absence of a palpable tumor suggests the possibility that there may be some estrogenic stimulation of the breast. Sometimes under such a stimulation one breast enlarges with but little enlargement of the other. In some males with hypogonadism there may be a slight enlargement of one or both breasts, possibly as a result of a disturbance in the estrogen-androgen ratio. The fact that the swelling is periodic makes it desirable to search for a tumor which produces estrogenic material. This might be present in either a testis or an adrenal gland. It would be desirable to know whether or not any breast tissue is palpable and whether or not there has been any enlargement of the areola and nipple. Such changes would strongly suggest the likelihood of estrogenic stimulation.

EXCRETION OF SODIUM CHLORIDE IN URINE

To the Editor:—Please explain the value of measuring the total twenty-four hour excretion of sodium chloride in the urine. What is normal, and what do a low excretion and a high excretion indicate? What is the most satisfactory method of determining the total sodium chloride excretion for the general practitioner? M.D., Michigan.

ANSWER.—The determination of the twenty-four hour renal excretion of sodium chloride (chloride calculated as sodium chloride) is little used in the clinic at the present time. The normal adult range of sodium chloride excretion varies from 8 to 15 Gm., although values from 5 to 20 Gm. may be found, the average output being close to 10 Gm. per day. Normally this represents the salt intake of the previous twenty-four hours.

Low chloride excretion is generally associated with a hypochloremia, and a study of the plasma chloride and bicarbonate level is more useful as a rule than the quantitative determination of the urinary chloride excretion, although both determinations may be done. In pyloric obstruction and other conditions in which excessive vomiting occurs, the level of the plasma chloride may drop to the renal threshhold value, in which case urinary excretion of chloride practically ceases. Very low values are likewise encountered in pneumonia and other fevers; but, when the crisis has passed, the chloride excretion rapidly increases and for a short period may exceed the normal output. This is a favorable prognostic sign. In cardiorenal conditions both hyperchloremia and hypochloremia may occur, but the picture is so complicated that no generalizations regarding chloride excretion can safely be made. An excessive loss of chloride and sodium in the urine occurs in adrenal cortex insufficiency (Addison's disease) and a test for the diagnosis of this condition has been proposed on this basis.

A simple and sufficiently accurate method for the estimation of chloride in urine has been described by Samuel C. Harvey, The Quantitative Determination of the Chlorides in the Urine (*Arch. Int. Med.* 6:12 [July] 1910).

ORGANIZATIONS OF LARYNGECTOMIZED PATIENTS

To the Editor:—I understand that there is a "Lost Chord Society," membership in which is based solely on successfully undergoing a laryngectomy. Where are the headquarters of this society and who are its officers? Where can a patient who has had a laryngectomy receive information on artificial voice aids? M.D., California.

ANSWER.—The Lost Chord Society has not been identified. The "Anamilo Club" of New York, which was organized at the National Hospital for Speech Disorders, is composed of persons who have had their larynx removed. At the request of the attending surgeon a special committee of the club calls on patients who contemplate this type of operation. Artificial larynxes are manufactured by Otto Roberts, 705 Spivey Building, St. Louis, and by the Illinois Bell Telephone Company. Information can be obtained from Mrs. Tillie Brinkman, 505 West Belmont Avenue, Chicago.

ACTION OF DEHYDROCHOLIC ACID

To the Editor:—Is there anything that will dissolve gallstones clinically? What action has D-cholic acid on preformed stones? Willis P. Baker, M.D., Santa Ana, Calif.

ANSWER.—Nothing has been found that will dissolve gallstones clinically. Dehydrochloric acid (D-cholic) is a potent hydrocholeretic agent which will dilute bile by increasing its water content and volume. Dilution of the bile and frequent emptying of the gallbladder are measures which one might reasonably expect to reduce the likelihood of the formation of calculi under certain conditions. The use of bile salts and frequent fat feeding in the management of patients with biliary tract disease has been discussed recently:

Brown, Clarence F. G., and Dolkart, Ralph E.: Ketocholanic Acids in the Medical Management of Low Grade Gallbladder Disease, THE JOURNAL, Feb. 6, 1937, p. 458.

EFFECTS OF CHOLAGOGUES ON CORONARY OCCLUSION

To the Editor:—Would there be any harm if a cholagogue, such as "Depropanex," should be given to a patient with coronary thrombosis because of a mistaken diagnosis? Clifford W. Atherton, M.D., Stambaugh, Mich.

ANSWER.—Cholagogues in general will not have any deleterious effect on patients with coronary thrombosis. However, unless given in the event of a mistaken diagnosis, they should be avoided.

Depropanex is a deproteinated pancreatic extract free from insulin, histamine and acetylcholine. It relaxes muscle spasm and depresses sympathetic nervous system sensitivity. It is used chiefly in the treatment of intermittent claudication and to promote ureteral relaxation. It probably would not have any harmful effect on a patient with coronary occlusion.

INFLUENZA VACCINES

To the Editor:—Is there any evidence that one type of influenza virus vaccine is superior to another? I refer to the calcium phosphate absorbed type manufactured by Parke, Davis and Company and the regular or "Armed Services" type produced by Eli Lilly and Company. An industrial group is to be immunized and I wish to reassure it as to the potency of the preparation. M.D., Pennsylvania.

ANSWER.—There is little information as to the comparative prophylactic value in human beings of different preparations of influenza vaccine. All preparations are licensed by the National Institute of Health and presumably should meet the same requirements for potency as determined through laboratory tests.

ULCERATIVE STOMATITIS

To the Editor:—While it is obvious that exhaustive discussions are beyond the scope of a section such as Queries and Minor Notes, the treatment accorded the subject of ulcerative stomatitis and gingivitis (The Journal Nov. 2, 1946) seems inadequate. To confine this discussion to the fusospirochetal variety is like limiting consideration of respiratory infections to abscess of the lung. The fact is, of course, that there are many other ulcerative inflammations of the oral mucosae and gums. Perhaps more important to the general practitioner, these stomatitides are often caused by, and sometimes are the leading presenting symptoms of, blood dyscrasias, nutritional deficiencies, exanthems, dermatoses and poisonings. In the majority of these cases, positive smears of fusospirochetal organisms are nevertheless recovered. It is the responsibility of the practitioner to differentiate between those of local origin and those which signal systemic disorders. In the one instance it is good practice to refer the patient to the dentist, in the other to establish the correct diagnosis as a guide to appropriate treatment. Even allowing for the incomplete résumé, the prominent therapeutic roles of dental prophylaxis and penicillin in primary fusospirochetal infection should not have been omitted. Leo Stern, D.D.S., Chicago.

MULTIPLE MYELOMA

A Review of Eighty-Three Proved Cases

EDWIN D. BAYRD, M.D.
Fellow in Medicine, Mayo Foundation
and
FRANK J. HECK, M.D.
Rochester, Minn.

One hundred years ago, in November 1845, Sir James Watson sent a test tube of urine obtained from a 45 year old tradesman to Dr. Henry Bence-Jones with an accompanying note inquiring as to the nature of a strange substance present in that urine. This substance, then called "animal matter," has since become known as Bence-Jones protein.[1] MacIntyre[2] reported this case in 1850 in the *Medico-Chirurgical Transactions*.

Dalrymple[3] examined and described pathologically two ribs of an affected patient and reported the condition as mollities ossium in 1846. However, von Rustizky[4] is said to have been the first to describe the condition under the title "multiples myelom" in 1873, and Kahler[5] is credited with having associated this disease with the occurrence of Bence-Jones protein in the urine.

Since these early reports additions have been made to the literature steadily and at a somewhat increasing rate as the facilities for diagnosis and a greater knowledge of the unusual manifestations of this affliction have become more widespread. The most signal effort to systematize the present knowledge of this disease was that of Geschickter and Copeland[6] in 1928, when they reviewed all of the cases of proved multiple myeloma appearing in the literature up to that time and added 13 of their own to bring the total up to 425.

This present study deals with 83 cases of multiple myeloma in which the diagnosis has been verified by examination of pathologic material. The study includes all such cases seen at the Mayo Clinic through December 1945. Forty-nine cases were confirmed by means of sternal aspiration, 26 by biopsy and 8 by necropsy. Ten patients who had apparently solitary intramedullary tumors (not included in the 83 cases mentioned) were also seen, and the condition was verified by biopsy. These will be considered separately, not as indubitable instances of solitary myeloma, but as too uncertain of being multiple to be included in the general series. Eleven additional cases of extramedullary, oronasal myeloma were also noted, but with the exception of 1 case in which the myelomas later became multiple these will not be included, as they have been fully reported elsewhere.[7]

When this subject was last reported on from the clinic,[8] 32 cases of pathologically confirmed multiple myeloma had been observed. The present group of cases was drawn from more than 350 in which a diagnosis of multiple myeloma had been made on clinical grounds. In many of these, the evidence was almost indisputable but, unfortunately, pathologic material was lacking. Because of newer improvements in technic, most of the cases of proved multiple myeloma have been recent ones. Eighteen were seen in one period of six months during 1945.

CLINICAL MANIFESTATIONS

Pain.—All investigators to whose works we have had reference have observed that pain was the outstanding feature and frequently the sole symptom of which patients who had this disease complained. In this study it was present in 86 per cent of cases (fig. 3) at the time of first admission of the patients, which makes it the most constant finding by far. The two regions most often involved were the thorax and the lumbar spinal segment. Its onset frequently dated from some strain or slight trauma such as "the time I bumped my chest on the corner of the desk" or from "last January when I strained my back shoveling snow."

This pain was found as a rule to be steadily progressive, though with daily and weekly variations, only occasionally undergoing any prolonged remission which would have brought it into accord with Geschickter and Copeland's pain cycle.[6] Batts[9] was likewise unable to fit the majority of his patients into such a pattern.

On the few occasions when a remission did follow the initial onset of pain the pain usually was induced subsequent to trauma.

The pain that these patients experienced was almost always aggravated by exertion, coughing and sneezing and eased by rest. Many patients said that if they did not move they felt all right. Pain in the night was not common, contrasting with other malignant states.

Associated with this pain there was occasionally noted a striking, exquisite, yet superficial tenderness. The lightest palpation over the involved regions was sufficient to elicit an immediate and extremely sharp response from the patient. This tenderness was not found to be due to pathologic fractures, but local fragility of bone may have been a factor.

[9] Batts, M., Jr.: Multiple Myeloma: Review of Forty Cases, Arch. Surg. **39**: 807-823 (Nov.) 1939.

The characteristics of this pain alone, its location and progression and the rest, ease and freedom enjoyed by the patient at night, actually suggested the proper diagnosis to us clinically on one occasion. However, as a rule the clinical findings are entirely nonspecific.

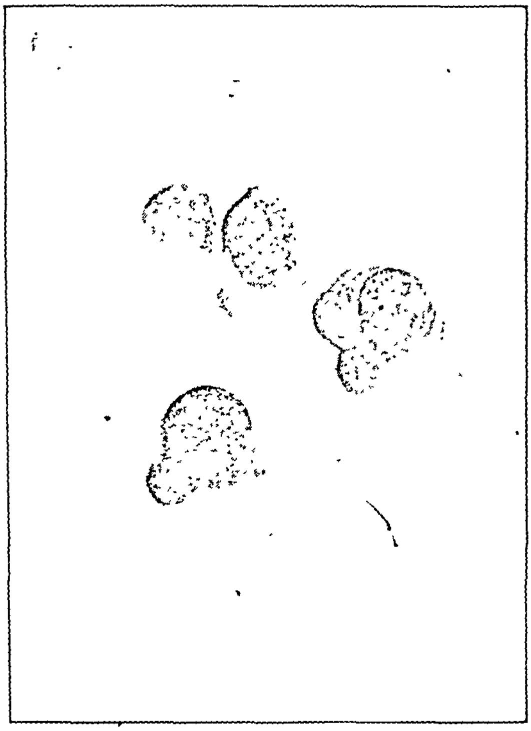

Fig. 1.—Smear of sternal marrow from same patient as in figure 4. Note contrast between the case illustrated in figures 1 and 4 and the case illustrated in figures 2 and 5. In the former case there were extreme destructive changes in the skeleton but the bone marrow showed much less change from normal than in figure 2; in the latter case the skeleton did not reveal any gross abnormalities but the bone marrow was characteristic of extremely malignant multiple myeloma.

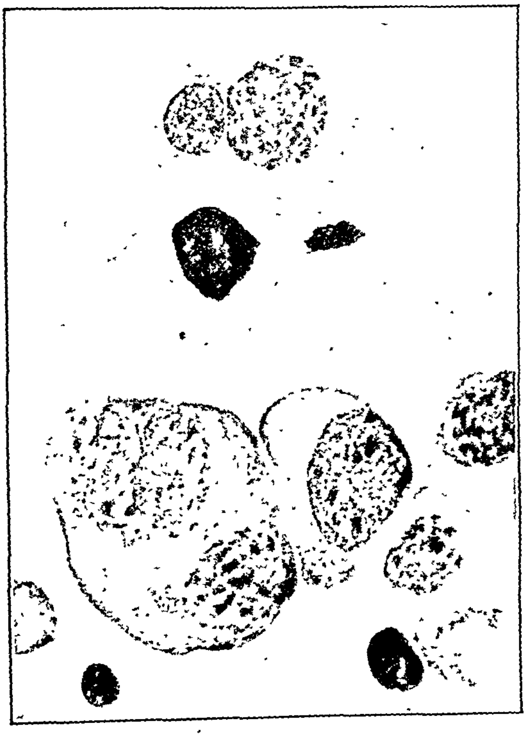

Fig. 2.—Smear of sternal marrow from same patient as in figure 5. The bone marrow was characteristic of extremely malignant multiple myeloma.

In 10 per cent of instances the pain had a rootlike distribution, often sciatic, and was usually found to be associated with compression of one or more vertebrae.

Fracture.—Pathologic fracture was encountered in a surprisingly small number of these cases (16 per cent), although occasionally evidence of old fracture of the ribs was present on roentgenologic examination of the thorax. When it was observed, the fracture usually involved the proximal third of the femur or the ribs, which is to be expected, since the disease primarily is one of the red bone marrow. These figures do not include compression, or "compression fractures" of the vertebrae.

Neurologic Manifestations.—Neurologic manifestations, such as root pain, as mentioned previously, and paraplegia, often a rather early development, were encountered in 12 cases (14 per cent). Once paralysis intervened, the outlook was definitely poor, although one of our patients lived for seven and a half years following laminectomy after the onset of paraplegia.

Bleeding.—Several writers have mentioned abnormal bleeding,[10] largely from the nose and gums. It is not as a rule associated with any defect in the clotting factors, except possibly of clot retraction. It is, however, almost invariably accompanied with a high concentration of serum globulin.[10h] In Schumacher's case the concentration of protein was 23.27 Gm. in 100 cc. of serum, and that of globulin was 16.02 Gm. Abnormal bleeding was observed in 6 instances in our series, and in 2 it was a distressing and most troublesome symptom, so much so that 1 of these patients received radium therapy locally in an endeavor to stop it. In all these cases the serum protein and serum globulin were appreciably increased, the lowest being 8.1 Gm. of protein in 100 cc. of serum and the highest, 14.1

Gm. No correlation with Bence-Jones protein could be obtained, however, as in 2 of the 5 cases the reaction for Bence-Jones protein was negative.

Formation of Tumor.—Formation of tumor was noted rather infrequently as compared to Batts's series, being found in only 10 cases, with a distribution as follows: clavicle, 3; skull, 2; humerus, 1; ribs, 2; sacrum, 1, and sternum, 1.

Pulmonary and Gastrointestinal Symptoms.—Pulmonary and gastrointestinal symptoms were no more frequent than one might have expected in a group of debilitated persons in this age range, and we were unable to develop any pattern of association such as suggested by previous authors.[6]

In 82 of the cases reported, roentgenograms were available. In 64 of these (78 per cent) multiple lesions were demonstrated. The whole skeleton was seldom roentgenographed, so that an attempt to indicate the relative frequency with which various regions were involved would be subject to obvious error. However, among 64 patients for whom multiple lesions were demonstrated on roentgenography, 58 had roentgenograms of the skull, of which 72 per cent were positive; 53 had roentgenograms of the thorax, 70 per cent of which showed such changes, and 51 had roentgenograms of the spinal column, 53 per cent of which showed the same discrete osteolytic regions.

As stated previously, pathologic fractures were noted in only 16 per cent of the patients in this series

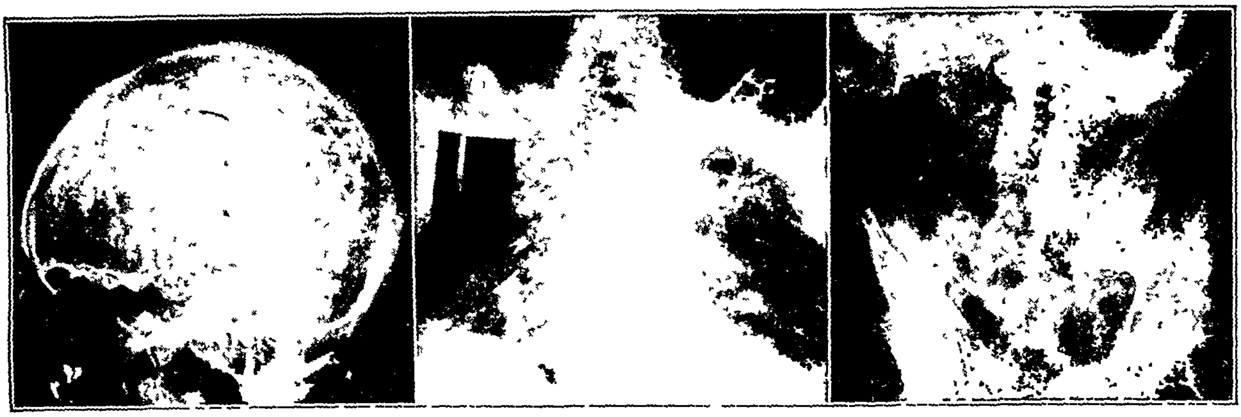

Fig 4.—Extreme destructive changes in the skeleton of a patient who had multiple myeloma

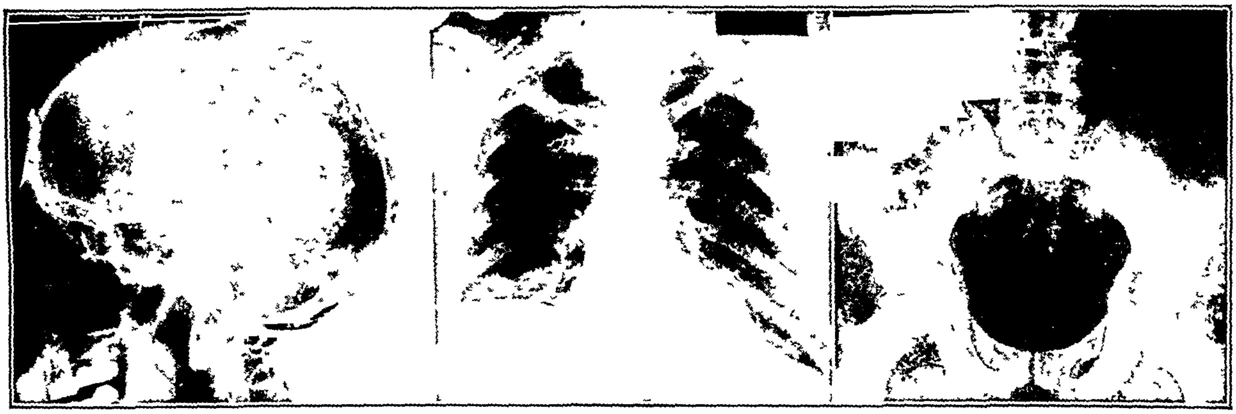

Fig 5.—Skeleton of a patient who had multiple myeloma There are no gross abnormalities

Age and Sex—The average and median ages of these persons were virtually the same, approximately 57 years, which agrees closely with the reports of others[11] There was an age span of 20 years on either side. The eldest was 78 and the youngest was 37 years of age. Men outnumbered women by about 3 to 1: men 76 per cent, women 24 per cent.

ROENTGENOGRAPHIC CHANGES

Discrete osteolytic regions in the skeleton of an adult man, especially when multiple, are almost always presumptive evidence of multiple myeloma. This is the so-called classical picture produced in the bones by this disease as it appears in the roentgenogram (figs 1 and 4). When it occurs, it should be substantiated by further appropriate diagnostic measures.

Other changes which occur with appreciable regularity are chiefly noted in the spinal column and include osteoporosis, compression of the vertebral bodies and ballooning of the intervertebral disks. These changes in themselves, of course, are not nearly so suggestive of multiple myeloma as the punched-out, osteolytic lesions, but in conjunction with an excessively high erythrocyte sedimentation rate, for example, their significance is notably enhanced.

These changes, usually found together, were noted in 21 cases, or 26 per cent of the whole group for which roentgenograms were available. In 7 cases (9 per cent) they constituted the only changes seen.

In 12 per cent of these cases, in the majority of which the serum proteins were elevated and inversion of the albumin-globulin ratio, excessive formation of rouleaux in smears of the peripheral blood and Bence-Jones proteinuria were present, no abnormalities of the osseous system whatsoever (figs. 2 and 5) were demonstrated by roentgenography (all roentgenograms included head, thorax and spinal column, and two thirds were complete). It should therefore be clear that multiple myeloma is not limited to those cases in which gross bony changes develop, and the diagnosis must in no instance be prejudiced by the absence of these changes.

BENCE-JONES PROTEIN

Historically, Bence-Jones protein is the most significant of the clinical laboratory findings in cases of this disease, even though it is now known to be found in other conditions and is observed in only somewhat more than half of the cases of proved multiple myeloma. Perhaps this figure will drop even lower as clinical appreciation of this disease is otherwise stimulated. However, it is most suggestive when it does occur, and has been the focus of much interest.

TABLE 1—*Cases in Which Bence-Jones Protein Was Present Not Associated with Multiple Myeloma*

Case	Sex	Age, Yrs	Roentgenographic Changes	Protein, Gm in Each 100 Cc of Serum	Albumin-Globulin Ratio	Sedimentation Rate, Mm in 1 Hr	Diagnosis
1	M	72	In spine, femur	.	..	...	Chronic lymphatic leukemia
2	M	60	In skull	6 8	1 31	161	At necropsy: adenocarcinoma of stomach
3	F	63	None	8 2	1 15	106	Carcinoma of kidney, grade 4
4*	M	59			.		Inactive pulmonary tuberculosis, prostatitis

* In case 4 Bence Jones protein was present in 10 0 and in 10 9 This patient was living in 1941 There was no evidence of multiple myeloma.

TABLE 2—*Relation of Bence-Jones Proteinuria to Albuminuria and Serum Proteins*

	Albuminuria		Serum Protein		
Bence Jones Proteinuria	Absent	Present*	Elevated	Low or Normal	Total Cases
Present	8	32	18	0	40
Absent	23	13	16	2	36

* Albuminuria, grade 2 or more (on the basis of 1 to 4), with or without casts and red blood cells

The evidence at hand seems to favor the conclusion that Bence-Jones protein is an extremely small globulin, or group of small globulins, with a molecular weight of approximately 30,000. Its small size may well account for its frequent occurrence in the urine as contrasted with the rarity with which it has been noted in the blood

Coley[12] found Bence-Jones protein in "about 8 per cent of all cases." His personal series included 16 cases. Batts[9] found it in 50 per cent; Ghormley and Pollock,[8a] reporting from the Mayo Clinic in 1939, found it in 35 per cent of proved cases, 51 per cent of their whole series. Geschickter and Copeland[6] in their review of 425 proved cases, including 13 of their own, noted an incidence of 65 per cent.

Bence-Jones protein has been reported[13] as occurring in the following conditions other than multiple myeloma: metastatic carcinoma of the bone, multiple sarcoma of the bone, senile osteomalacia, fibrocystic disease, comminuted fracture, tumor of the jaws, lymphatic leukemia, *myelogenous leukemia and polycythemia.* We have encountered it, unassociated with multiple myeloma, in the instances shown in table 1.

The nature of Bence-Jones protein and its mode and site of production have been the source of much speculation and investigation.

In a most extensive work on the subject Hopkins and Savory,[14] in 1911, found that Bence-Jones protein contains all the amino acids characteristic of a typical protein and is characterized by a high proportion of the aromatic groupings. They found it to have less power as an antigen than serum proteins and to contain less histidine than did globin. In their opinion it seemed to stand alone in respect to its chemical composition as well as its physicochemical properties. They suggested that it might be the result of an incomplete metabolism as well as an abnormal one, but that it was of endogenous origin.

Wintrobe and Buell,[15] *on the other hand, expressed* the belief that it is erroneous to conclude that temperatures of precipitation and solution of the protein are physicochemical constants, and stated that they are influenced by the concentration of the protein, p_H and presence of other compounds such as urea In their opinion, Bence-Jones protein is a "class" of substances. Yet they acknowledged that it had been isolated as a chemical individual in certain cases in which spontaneous crystallization had occurred on standing.

Bayne-Jones and Wilson[16] found Bence-Jones protein to be immunologically distinct from proteins of normal human serum.

Bence-Jones proteinuria appeared in 40 (53 per cent) of 76 cases in which the urine was tested. When this condition was present, it usually remained so, but this was not constant, and has been emphasized by many others.

Table 2 summarizes the relationship of Bence-Jones proteinuria to the serum proteins and albuminuria

PERIPHERAL BLOOD

Morissette and Watkins[17] have reviewed this aspect of the disease rather extensively in an investigation of 100 blood smears which, because of "greasiness"[18] or other reasons, were suspected of coming from patients who had multiple myeloma Fifty-six cases were found in which the diagnosis of multiple myeloma was the most acceptable from clinical and laboratory studies (in only 19 of these was the diagnosis pathologically confirmed). The significant hematologic findings in these 56 were (1) anemia, (2) excessive formation of rouleaux, (3) immaturity of both erythrocytes and leukocytes, (4) lymphocytosis, (5) eosinophilia and (6) presence of myeloma cells and atypical plasma cells

Anemia.—Anemia has been repeatedly noted as one of the important, frequently occurring features of multiple myeloma and has been ascribed to (1) bone marrow replacement, (2) toxic inhibition and (3) renal failure. None of these has been an entirely satisfactory explanation. But in any event the response to the usual therapeutic measures is generally disappointing.

[17] Morissette, L, and Watkins, C. H: Multiple Myeloma: Diagnostic Value of the Blood Smear, Proc Staff Meet, Mayo Clin. 17:433 440 (July) 1942.

[18] A smear of the peripheral blood was referred to as "greasy" if it appeared as though it had been made on a dirty or an oily slide

In this group anemia was common, 53 per cent of the patients having hemoglobin values, by the photelometer method, of less than 11 Gm. per hundred cubic centimeters of blood. Fifty-six per cent of the patients had an erythrocyte count of less than 4,000,000 per cubic millimeter of blood, and 25 per cent had an erythrocyte count of less than 3,000,000 per cubic millimeter. It will be noted, however, that the counts alone are as a rule worth little except as unexplained anemia may provoke further study.

Excessive Formation of Rouleaux.—Excessive formation of rouleaux in cases of multiple myeloma was first stressed by Reimann,[19] although he cited Hewson as having commented on abnormal formation of rouleaux in 1797. Many others have noted it since.

Considered as causes of this phenomenon are slow drying, presence of a hydrophilic colloid (acacia) and increased globulin with a reversal of the albumin-globulin ratio.

Frequently associated with formation of rouleaux is autohemagglutination,[20] which may appear in the red cell counting chamber, is associated with an elevated erythrocyte sedimentation rate and may make cross matching or typing impossible. Snapper[21] suggested carrying on this reaction in an incubator at 28 C. to overcome this tendency.

Excessive formation of rouleaux was noted in 38 of 63 cases (60 per cent) in which examinations of the peripheral blood were made. An extremely close correlation with increased serum globulin and an elevated erythrocyte sedimentation rate was noted. In no instance was increased formation of rouleaux noted in the presence of normal serum globulins, or normal serum protein levels, although it was not mentioned in 4 cases in which the proteins were elevated.

A corollary to formation of rouleaux is an elevation of the erythrocyte sedimentation rate to surprising heights. Our highest uncorrected rate was 176 mm. in one hour by the method of Westergren.

In 45 cases determinations of both the total serum protein and the erythrocyte sedimentation rate were made. In 36 of these there was an increased serum protein (more than 8.0 Gm. per hundred cubic centimeters), and in all but 1 there was a notably increased sedimentation rate, of 100 mm. or more in an hour (Westergren method, not corrected). In that 1 case the serum protein was 10.2 Gm. per hundred cubic centimeters, the albumin-globulin ratio 1:1.6 and the erythrocyte sedimentation rate 35. Of the 9 cases in which the serum protein was normal, in all but 2 there was an erythrocyte sedimentation rate of less than 58 mm. in an hour, and in only 3 of those did it exceed 28 mm. in an hour. Of the 2 mentioned, in 1 there was a sedimentation rate of 107 mm., with a serum protein of 7.8 Gm. per hundred cubic centimeters and an albumin-globulin ratio of 1.5:1.0, and in the other there was a sedimentation rate of 72 mm., with a serum protein of 6.5 Gm. and an albumin-globulin ratio of 3.5:1.0.

Leukocyte Count.—The leukocyte count is usually normal or somewhat low. In 80 per cent of our series it was less than 10,000 per cubic millimeter of blood, and in a third of the 80 per cent it was less than 5,000. However, a leukemoid reaction is fairly common, and on occasions it may be extreme, leading to rather high counts. Barr[22] reported a case in which there was a leukocyte count of 21,000. In Rosenthal and Vogel's[23] case (number 13) the leukocyte count was 48,000. Foord and Randall[10f] reported a case proved by necropsy (number 1) in which there was 18.37 Gm. of protein per hundred cubic centimeters and the leukocyte count was 131,000 terminally with 2 per cent leukoblasts and stem cells, 12 per cent myelocytes and 31 per cent eosinophils.

Morissette and Watkins[17] noted that eosinophilia was occasionally encountered in cases of multiple myeloma, as was lymphocytosis. In this series, however, only 1 case was noted in which significant eosinophilia had been recorded. Leukocytes numbered 6,800 in each cubic millimeter of blood, and 45 per cent of them were eosinophils. Lymphocytosis in these cases was never more than moderate and by no means constant.

Myeloid Immaturity.—Myeloid immaturity as far back as the stem cell was observed with notable frequency. In 41 per cent of 63 cases in which smears of the peripheral blood were submitted for study there was myeloid immaturity to the myelocyte at least. In 20 per cent stem cells were also seen.

Myeloma Cells.—Since Foa,[24] in 1904, and Schridde, who first observed myeloma cells or atypical plasma cells in a case of Aschoff's[25] in 1906, many observers[26] have described them in the peripheral blood stream in cases of multiple myeloma (fig. 6). This may reach the extreme that it did in 1934 in the case of a 49 year old man in which Osgood and Hunter[10c] found 45 to 54 per cent of "plasma cells." This man's spleen was palpable, and he had a leukocyte count ranging from 15,700 to 34,050 per cubic millimeter of blood. His serum protein was elevated to 8.79 Gm. per hundred cubic centimeters, and his albumin-globulin ratio was materially reversed. He had an erythrocyte sedimentation rate of 95 mm. in fifteen minutes, but had no Bence-Jones proteinuria, and only finely granular regions of decalcification in his skull were observed by roentgenologic examination. At necropsy the plasma cells made up 50 per cent of the cellular elements of the bone marrow and showed prominent nucleoli.

Osgood and Hunter considered this to be a true instance of plasma cell leukemia and not multiple myeloma with myeloma cells in the peripheral blood. They held splenomegaly, epistaxis, bleeding from the gums and the clinical course which this patient pursued to be of the type characteristic of leukemia. As further evidence they cited the lack of Bence-Jones proteinuria, of "typical" defects of the bone in the roentgenograms, bone pain and bone fragility. Others have felt that this is a distinction of degree only, not of kind. With this we would concur.

(*i*) Morissette and Watkins.[17]

Significant splenomegaly has been noted in cases of typical multiple myeloma,[27] as has hemorrhage, and it should be apparent from the cases reported herein as well as from the reports of others that the absence of Bence-Jones proteinuria and of findings referable to the osseous system is far from conclusive.

Moreover, Osgood and Hunter themselves took note of the transitional cases between their own and the usual multiple myeloma with myeloma cells in the peripheral blood.

In 1937 Reiter and Freeman[28] reported the case of a woman, 66 years of age, in which there were 72 to 74 per cent of plasma cells in the hepatic and pancreatic vessels at necropsy. During life the patient had manifested weakness, had been treated for pernicious anemia and had not had any roentgenographic studies of her skeleton.

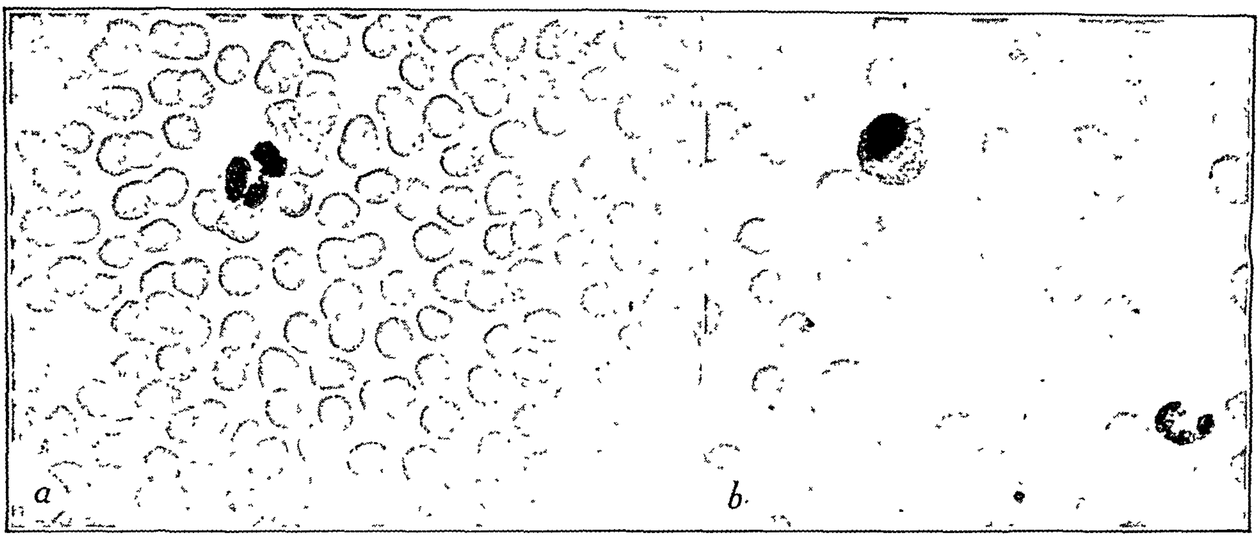

Fig. 6—Smears of the peripheral blood. (a) Normal blood; (b) blood in a case of multiple myeloma exhibiting excessive formation of rouleaux and a myeloma cell (upper left).

Recently Meyer, Halpern and Ogden[29] reviewed all the known cases of multiple myeloma in which there were plasma cells in the peripheral blood and all the purported cases of plasma cell leukemia, of which they listed 4. In a careful consideration of these cases they expressed doubt that any were actually cases of true plasma cell leukemia. They rejected these cases largely on the ground that the absence of osseous lesions had not been adequately established.

They then presented data on a case of their own of "acute plasma cell leukemia" with hemorrhage and purpura, the patient being a 67 year old woman. There were 11,000 to 31,000 leukocytes per cubic millimeter of blood containing up to 44 per cent "plasma cells," 11 Gm. of total serum protein per hundred cubic centimeters and an inverted albumin-globulin ratio. There was no Bence-Jones proteinuria, and the "complete" skeletal roentgenograms demonstrated "no abnormal bone changes." The spleen, liver, lymph nodes and bone marrow were found to be extensively involved at necropsy. Here stress was laid on the absence of tumors of the bone and Bence-Jones proteins as being evidence against multiple myeloma, whereas the bleeding, the visceral involvement and the clinical course were noted as being characteristic of leukemia. The elevated serum protein was discounted as not diagnostic of multiple myeloma.

Because of this Meyer, Halpern and Ogden expressed the belief that their case justified the designation of acute plasma cell leukemia, although they considered it to "complete the chain in the analogy to lymphoid tumors" such as lymphoma and lymphatic leukemia.

However, since we know that otherwise typical multiple myelomas may occur without discrete bony lesions, without Bence-Jones proteinuria, or with splenic and nodal involvement,[30] with bleeding and purpura and with a high percentage of plasma or myeloma cells in the peripheral blood, we cannot feel that this case represents anything other than the leukemic phase of multiple myeloma. It is not clear that any useful purpose is served by creating the impression that "plasma cell leukemia" is a separate entity.

Morissette and Watkins found atypical plasma cells and myeloma cells in 41 of the 56 cases of multiple myeloma which they studied (73 per cent). In the present series no special effort was made to review the blood smears for myeloma cells. As they were reported by the initial examiner they occurred in only 10 per cent of cases.

One of these patients had 7.5 per cent myeloma cells in his peripheral blood, and another (to be reported on in greater detail separately) with the clinical picture of leukemia had 41.5 to 48 per cent myeloma cells in his peripheral blood.

Of the other observations on the peripheral blood one has been mentioned in connection with the bleeding tendency that some of these patients have, namely, poor clot retraction. This has been observed occasionally among the patients of the present study.

30. Ghormley and Pollock.[6a] Jackson, Parker and Bethea.[10b] Barr.[22] Lowenhaupt.[27]

Rosenthal and Vogel[23] noted thrombopenia in 5 of their 13 cases. We have not observed it with any appreciable frequency, but it should be looked for.

It is also of interest to note that on one, two or three occasions a robin's egg blue background has been observed in the blood smear when stained by the usual method with Wright's stain. These have all been associated with unusually high globulins, but the blue background and the concentration of globulins do not appear to bear a strictly quantitative relationship.

PROTEINS

Ellinger[31] is said to have reported abnormal serum proteins first in cases of this disease in 1899. Feller and Fowler[32] listed 52 cases of elevated serum protein in multiple myeloma as collected through 1936 and noted that most of them had appeared since 1928. By 1937 the number had risen to 60,[33] and Jeghers and Selesnick[34] had concluded that hyperproteinemia occurred in between 50 and 60 per cent of cases of multiple myeloma.

Causes of hyperproteinemia, which almost always mea [illegible] as observed by several authors,[35] are

The reason for this increased serum protein level in cases of multiple myeloma is not known, although the bone marrow and the liver have both been implicated. In 1 of our cases the myeloma cells in the bone marrow peculiarly resembled reticulum cells involved in a storage disease.

The only unusual observation with respect to the spinal fluid of which we are cognizant is that reported in the Cabot case, number 20031,[36] in which the gold sol curve was 5555555554 and the protein was 95 mg. per hundred cubic centimeters.

Precipitation of this protein by Hayem's solution[37] and by cold[15] has been noted occasionally. The relationship between the elevated serum globulin, formation of rouleaux and an increased sedimentation rate has been mentioned.

Of the 83 cases in this series estimations of total serum protein were made in 55 cases. In 40 of these (73 per cent) the concentration of protein was elevated above a level of 8.0 Gm. per hundred cubic centimeters. In all but 3 of these there was a reversal of the albumin-globulin ratio. The highest serum protein value obtained was 14.1 Gm. per hundred cubic centimeters, with an albumin-globulin ratio of 1:3.3. The most disproportionate ratio (1:6.7) occurred with a serum protein of 11.8 Gm.

In 40 cases in which the concentration of protein in the serum was elevated there were multiple roentgenographic changes in 73 per cent, osteoporosis in 15 per cent and no roentgenographic changes in 12 per cent. The concentration of hemoglobin was less than 13.5 Gm. in 100 cc. of blood in all cases and less than 11 Gm. in 90 per cent of cases. Bence-Jones proteinuria was present in 56 per cent of cases. The sedimentation rate (Westergren method) was 100 mm. or more in one hour in 97 per cent of the 40 cases.

CALCIUM

In 1936 Gutman and his co-workers[38] reviewed the cases of multiple myeloma in the literature in which determinations of blood calcium had been made. Seventy-two cases were found at that time, and to these they added 6 of their own. The calcium values as recorded were elevated (more than 12 mg. per hundred cubic centimeters) or said to be elevated in 34 instances (44 per cent). The highest value was 20.0 mg. per hundred cubic centimeters. In 4 of their 6 cases the levels were elevated.

As a rule the serum phosphorus is normal or slightly elevated and the phosphatase is normal or somewhat increased. Two different authors reported serum phosphorus values of 6.8 mg. per hundred cubic centimeters.

Table 3.—*Causes of Hyperproteinemia*

Cause	Frequency of Hyper-proteinemia	Protein, Gm. in Each 100 Cc of Serum	Author
Kala azar	....	10 54	Wu
Syphilis	....	9.37	Wu
Renal carcinoma	.. .	.....	Peters and Eisenman
Lymphosarcoma	..	.....	Feller and Fowler
Schistosomiasis	50%	8 to 10	Meleney and Wu
Leprosy (32 cases)	80%	Over 8	Frazier and Wu
Cirrhosis	. .	11.46	Snapper

Lymphogranuloma venereum	62 of 67 cases	Over 8	Kagan
Dehydration	....	.....	Kagan
Monocytic leukemia		. . .	Kagan
Boeck's sarcoid		. .	Kagan

Table 4.—*Data for Cases in Which Serum Calcium Was Greater than Normal*

Case	Calcium, Mg in Each 100 Cc of Serum	Phosphorus, Mg in Each 100 Cc. of Serum	Phosphatase, Bodansky Units	Protein, Gm in Each 100 Cc. of Serum
1	13 8	2 9	...	....
2	12.2	3 0	...	7.7
3	15 6	3 8	0 9	13.5
4	12 5	3 6	2 4	11 4
5	15 7	6 6	..	8 1
6	15 9	4 0	...	6 4
7	12 7	2 9	1.9	9.5
8	12 9	6 0	2.2	6 5

In our series determinations of serum calcium were obtained in 41 instances, of serum phosphorus in 36 cases and of alkaline phosphatase (Bodansky) in 24 cases. In only 8 instances did the serum calcium exceed 12.0 mg. per hundred cubic centimeters in this group (20 per cent). The highest values were 15.6, 15.7 and 15.9 mg. per hundred cubic centimeters.

The serum phosphorus averaged 3.41 mg. per hundred cubic centimeters, ranging from 0.8 to 14.3 mg. per hundred cubic centimeters. Twenty-eight of the 36 estimations were between 0.8 and 4.2 mg. per hundred cubic centimeters.

The alkaline phosphatase ranged between 0.8 and 12.3 units (Bodansky) and averaged 3.02 units. Twenty-one of the twenty-four determinations were found to be within 0.8 and 3.6 units and averaged 2.13 units.

When those cases are listed in which the serum calcium was found to be elevated (table 4), it will be seen that the values for serum phosphorus were either normal or slightly elevated and that the phosphatase activity, when noted, was normal to low. It will also be noted from table 4 that no apparent correlation exists between the serum calcium level and that of the serum protein.

RENAL COMPLICATIONS

Many patients who have multiple myeloma are first given a diagnosis of nephritis, and many more patients manifest renal impairment at some stage of their disease. In some cases uremia is the terminal event. The presenting complaint may be that "my urine is loaded with albumin."

In Bell's review of the subject in 1933[39] he stated that the only direct effect of multiple myeloma on the kidneys was obstructive, owing to tubular casts of Bence-Jones protein and atrophy. He expressed the opinion that Bence-Jones proteinuria per se does not have an injurious effect on either the glomerulus or the tubule. Others have noted this same lesion, which has been called "intranephritic hydronephrosis."[26e]

In those cases in which Bence-Jones proteins did not seem to be incriminated, Bell felt that renal failure could be explained on another basis than multiple myeloma.

In 5 of our cases albuminuria was the outstanding symptom on admission. Of the few patients that have died while still here, uremia was a part of the terminal episode in 3 instances.

Fifty-one patients in this group (61 per cent) exhibited varying degrees of renal impairment as evidenced by albuminuria (grade 2 or more on a basis of 1 to 4) with or without casts, red blood cells or an elevated blood urea. A third of these patients had albuminuria alone.

SOLITARY MYELOMAS

In the 10 cases represented in this group of solitary myelomas, the myelomas are not unequivocally solitary, but they are doubtfully multiple, and because these lesions tend to bear a somewhat better prognosis than the multiple ones they have been reviewed separately. Another group of 11 cases of solitary myelomas involving the oronasal cavities have recently been reported elsewhere.[7]

However, this separation of multiple and solitary myelomas is to some degree artificial because they are probably all a phase in the same disease in which the plasma cell leukemias represent one extreme and the solitary myelomas the other. Furthermore, "solitary myeloma" is frequently an inexact designation, since a single lesion determined by roentgenography, even when a sternal aspiration has been negative in result, is not complete assurance of a solitary process.

Tennent,[40] in a review of 49 solitary myelomas of bone which he found in the literature, stated that 30 per cent of them became generalized. This is somewhat at variance with the opinion expressed[41] that this form of myeloma is benign. Likewise Figi, Broders and Havens[7] have emphasized the malignant character of the extramedullary myelomas which they reported.

In King's case[42] of a solitary intraosseous lesion, multiple myeloma manifested itself four years later. Jackson and Parker[10b] reported a case (number 1) of an extramedullary myeloma which became generalized ten years after the patient's initial biopsy.

In Geschickter's case[43] of a solitary myeloma, demonstrated in the left hip by roentgenography, the patient pursued a progressive downhill course regardless of the fact that no generalized disease could be demonstrated.

Cutler and others[44] collected reports of 12 cases of solitary intraosseous myeloma from the literature and 5 from the bone registry, and added 1 of their own. Of the 5 patients having Bence-Jones proteinuria, 4 showed a generalized spread within two months to four years thereafter. Of those without Bence-Jones proteinuria, 1 was alive and apparently well four years later, 1 nine years later and 1 ten years.

Pasternack and Waugh[45] reported a case in which the patient was alive and without a generalized spread of the disease after seven and a half years.

In 1943, Hellwig[46] collected the cases of extramedullary plasma cell tumors from the literature and added 1 of his own for a total of 128 cases. Of the cases that he collected 47 were conjunctival, benign and probably inflammatory. Four were nodal. Two of these were associated with typical multiple myeloma and 1 with other involved viscera. Thirteen involved other organs. Sixty-three were in the air passages. These Hellwig divided into five groups. Group 1 included 26 patients who had single tumors which were felt to be "noncancerous." None of the patients had Bence-Jones proteinuria and none of the tumors was known to have become generalized. The nine tumors in group 2 were "noncancerous and multiple." Three of 7 recurred. The tumors in group 3 were "cancerous without metastasis." Of the 10 patients most died within a year. One was alive after twelve years. In group 4 there were 9 patients, with tumors "cancerous with metastases in nodes." All patients died shortly thereafter. In group 5 there were 9 patients, with tumors "cancerous with metastases to bone." All patients died, but over a period of twelve years. Bence-Jones protein appeared with involvement of bone.

> In 1 of the cases of oronasal myeloma reported by Figi, Broders and Havens[7] from the Mayo Clinic in June 1945, the patient was a man of 60 years of age who came to the clinic in July 1934, complaining of a choking sensation in his throat. A myeloma measuring 4 by 3 by 2 cm. and involving the right tonsil was removed, and two courses of roentgen therapy were administered. His urine did not show evidence of Bence-Jones protein.
>
> In June, 1942, the patient returned with a six weeks' history of pain in his sternum and ribs anteriorly, and of a loss of 8 to 10 pounds (3.6 to 4.5 kg.). A roentgenogram of the thorax revealed multiple osteolytic lesions. Bence-Jones protein was demonstrated in his urine. He died four months later.

It therefore becomes apparent that the benignancy of these solitary myelomas is only relative, that they are intimately associated with what it is customary to refer to as multiple myeloma, if not indeed a part of the same process, and that fairly frequently the full-blown picture of multiple myeloma develops, even following successful excision of the local lesion without local recurrence.

Another of our patients, a man of 44 years, registered at the clinic in December 1944, because albumin had been discovered in a routine examination of the urine. It contained Bence-Jones protein when examined at the clinic, although roentgenograms of his skull, thorax, spinal column, pelvis and femurs revealed only a small, single defect in his skull. However, a smear of the sternal marrow yielded 6 per cent of myeloma cells, to establish as multiple myeloma what otherwise might have passed for a solitary myeloma. A more recent report on the patient from his home physician stated that within three months after the patient had left the clinic a second lesion had appeared in the femur and 95 per cent of myeloma cells were present in a smear of the sternal marrow. This is an instance of an apparent, not a real solitary myeloma.

It may be of some interest to note here also that since we have begun doing sternal aspirations routinely on these patients, we have not encountered any solitary myelomas. This does not mean that we doubt their occurrence. We do, however, feel that more of the so-called solitary myelomas will be found to be part of a diffuse process as more care is taken to establish the diagnosis.

The pertinent available data on the 10 cases of solitary lesions are listed in table 5. In no instance had the additional confirmation been obtained of a sternal aspiration with negative result.

DIAGNOSIS

The various clinical and laboratory features of this disease are striking, and the occurrence of multiple osteolytic lesions of the bone, Bence-Jones proteinuria and hyperproteinemia is strongly suggestive evidence for the presence of multiple myeloma. However, every effort should be made to confirm this with pathologic material for the sake of accuracy of prognosis and suggestions as to an outline of treatment. To this end, because of its simplicity and broad diagnostic range, the method of sternal aspiration readily lends itself. Beizer and his co-workers,[20e] Young and Osgood,[47] and others have discussed this in detail elsewhere.

With regard to the use of sternal aspiration it must be mentioned that a negative result is not always adequate evidence for excluding the possibility of multiple myeloma. The changes in the bone marrow may be irregularly distributed rather than diffuse, and the results on repeated aspirations are not uniform. In 1 instance a third aspiration of marrow was necessary to secure a diagnostic specimen.

TREATMENT

Unfortunately, there is as yet nothing of proved worth, either curative or palliative, to be offered to patients who have multiple myeloma. Coley's [12] toxin, roentgen therapy and radioactive phosphorus have been tried by ourselves and others with indifferent results, though occasionally with relief of pain. More recently radioactive strontium has been used. Nothing is known of the comparative value of this substance and radioactive phosphorus at present.

One of our patients was put on a high calcium regimen [48] in 1941 and wrote two years later that she was mowing the lawn and doing her own housework and "felt better than she had in ten years." When last heard from in October 1945, fifty-one months after the diagnosis had been established, she was hospitalized for a fracture of her left femur and had not taken any calcium for two years. However, we have reason to believe that this patient had a more chronic form of the disease than most.

Batts [9] reported on 3 patients who underwent laminectomy for decompression of the spinal cord after the development of paraplegia. One died postoperatively, 1 reported herself well at the end of three months and 1 died of pneumonia four years after his operation without evidence of recurrence. A patient on whom operation was performed at the clinic was relieved of paraplegia by removal of an apparently local lesion which had caused compression of the first lumbar vertebra. The patient lived seven and a half years thereafter. The ultimate cause of death was not known.

PROGNOSIS

Fifty-five patients in this group were followed until the time of their death. For 11 others who are still living, follow-up reports are available.

Of the 55 who died, the average duration of the disease from the onset of symptoms was eighteen and eight-tenths months. The median duration was fifteen months. The longest period of survival was eighty-four months, and the shortest was one month.

The usual duration of symptoms before the patient's first visit to the clinic was eight months, and the expectation for survival thereafter averaged ten months and varied between one week and seventy-two months. The median was somewhat less, with 50 per cent of the patients failing to live throughout the first half year afterward. No correlation between life expectancy and the form of treatment was noted.

In 27 cases in which the serum proteins were found to be elevated the average duration was eighteen and one-tenth months and the average survival after examination was six and one-tenth months.

47. Young, R. H., and Osgood, E. E.: Sternal Marrow Aspirated During Life: Cytology in Health and in Disease, Arch. Int. Med. **55**: 186-203 (Feb.) 1935.

48. Calcium gluconate and calcium lactate in equal parts, 20 grains (1.3 Gm.), was administered four times a day for one month, three times a day for one month and thenceforth twice a day. Calcium gluconate, 10 cc. of a 10 per cent solution, was administered intravenously every other day for sixteen doses simultaneously with the beginning of oral administration.

Of 30 patients having Bence-Jones proteinuria who were followed, the duration of the disease averaged twenty-three and seven-tenths months and ranged from one month to seven years.

Although, as can be seen, neither the serum protein nor Bence-Jones proteinuria has any prognostic value, we believe that a distinction between acute and chronic multiple myeloma may be made cytologically on the basis of the smear of the sternal aspiration. This we hope to be able to report on in detail later.

CAUSATION

At present there exists a rather wide diversity of opinion regarding the nature of the parent myeloma cell and the types of multiple myeloma to be found.

It has been suggested that myeloma cells arise from supportive tissue, not marrow,[49] that they arise from myeloblasts,[50] erythroblasts,[51] osteoblasts [52] or the reticuloendothelial cells,[53] or that they are modified lymphoid and develop through a dysplastic plasma cell line, which rarely matures and probably does not produce a true plasma cell when it does mature.

Many observers have felt that in addition to the "plasma cell" type of myeloma, "plasmacytoma," there exist "lymphocytomas,"[55] "myeloblastomas," "erythroblastomas"[56] and "myelocytomas."[57] Christian, who has been repeatedly quoted as supporting the plasma cell type of multiple myeloma, has since stated in a discussion of a paper presented by Giffin, Beizer and Hall[58] that the type of myeloma cell may range between the myelocyte on one hand and the plasma cell on the other. Rosenthal and Vogel's[23] case of a myelocytoma (number 13) is the only case of multiple myeloma of which we have knowledge that was identified as other than a plasma or myeloma cell type by the method of sternal aspiration. All others were made from fixed tissue sections. Even in Rosenthal and Vogel's case the few myeloma cells present were essential to the diagnosis. This implies the possibility that it was actually a myeloma cell type with a leukemoid reaction and that further efforts to secure specimens of marrow might have yielded a different spread of cells.

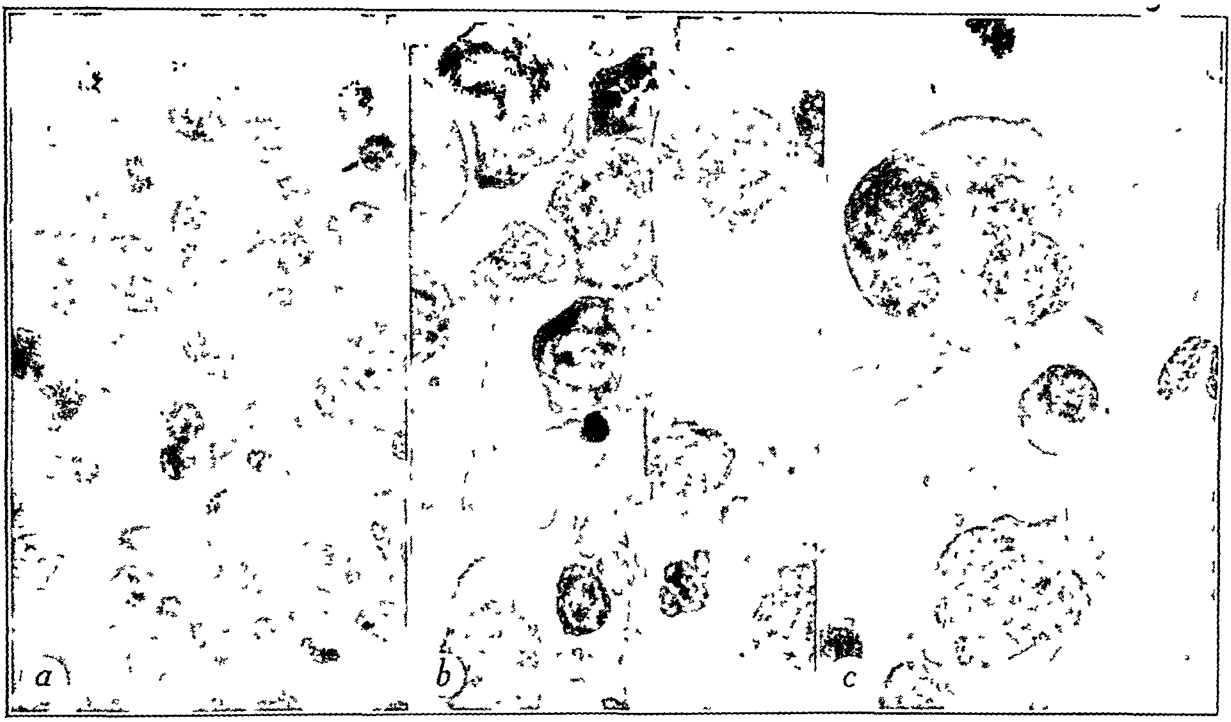

Fig 7.—(*a*) Fixed section of the sternal marrow presents a picture such as is usually referred to as a "myeloblastoma," whereas smears of the same marrow (*b* and *c*) reveal a highly malignant "plasma cell" myeloma.

tissue.[54] Although we have seen myeloma cells which resembled immature red cells and others which looked like stem cells, we have felt that in more malignant lesions, where the younger cells occurred with greater frequency, we could trace their origin to the reticuloendothelial cells. Thus it seems likely to us that myeloma cells arise from the reticuloendothelial cells

In 1 case in this series the lesion was reported by the pathologist from a biopsy specimen as a myeloblastoma. In another, not included in this report, the lesion was previously considered to be a multiple myeloma occurring in a 4 year old child. The report at necropsy was multiple myeloma in which only myeloblastic cells were seen. A review of this case makes a diagnosis of leukopenic leukemia seem more probable.

Every one of the 49 cases so diagnosed by sternal aspiration has been without exception of the myeloma

cell type. One of the more recent of these was a myeloma cell type of a high degree of malignancy with many immature forms appearing on the smear of bone marrow. The fixed tissue sections of the same marrow for this patient resembled what has usually been referred to as "myeloblastoma" (fig. 7).

It is for these reasons that we have come to regard the myeloma cell as a specific type associated with multiple myeloma.

Some have disputed whether or not this disease is (1) a form of cancer, (2) a form of leukemia or (3) a form of lymphoma. Its various features give it a resemblance to each of the classifications mentioned, but as long as its clinical and pathologic manifestations are kept in mind, it is of little moment at this time which thesis one supports.

SUMMARY

The clinical and clinical laboratory data in 83 cases of pathologically confirmed multiple myeloma were reviewed, and the opinion is expressed that this disease is represented by a single cell type arising from the reticuloendothelial system in a dysplastic plasma cell line. Multiple myeloma is a uniformly malignant and usually rapidly fatal disease in its generalized form and ranges from the solitary to the leukemic stage at either extreme. Confirmation of the diagnosis is important, and sternal aspiration is most probably the method of choice. By use of this procedure some additional indications of chronicity or acuteness may be derived. Thus far an effective form of therapy has not appeared.

STILBAMIDINE AND PENTAMIDINE IN MULTIPLE MYELOMA

ISIDORE SNAPPER, M.D.
New York

Antimony compounds cure kala-azar, a disease which is accompanied with an increase in the globulin content of the serum.[1] Because of this association, antimony compounds have been tried in other diseases in which hyperglobulinemia occasionally occurs. These preparations have been given in Hodgkin's disease, leukemia and multiple myeloma, but until now favorable reports have not appeared in the literature.

Since 1939 diamidine compounds not containing antimony have been successfully employed in the treatment of kala-azar.[2] This report deals with the influence of two diamidine compounds, Stilbamidine (4,4-diamidinostilbene) and Pentamidine (4,4'-[pentamethylenedioxy]dibenzamidine),[3] on multiple myeloma, a disease in which increase of the globulin content of the serum is of frequent occurrence.[4]

For 13 patients with multiple myeloma the administration of Stilbamidine, combined with a diet low in animal protein, has had a favorable influence on the pain which is characteristic of this disease. For 2 patients with myeloma good results were obtained by the injection of Pentamidine. Until now, neither drug has influenced the course of multiple myeloma for patients who were fed a diet high in protein.

METHOD

Stilbamidine was given either intravenously or intramuscularly. The intramuscular route was chosen only when veins were not readily available for injection. For intramuscular injection the diamidinostilbene was dissolved in 5 cc. of 2 per cent solution of procaine hydrochloride. For intravenous injection, the compound was dissolved in 10 cc. of distilled water. The solution should not be autoclaved.

The dosage schedule was as follows: A first injection of 50 mg. was given, followed two days later by an injection of 100 mg. Thereafter 150 mg. was given, usually every other day but in some cases daily. At first the treatment was limited to fifteen injections of 150 mg. In the later cases the injections were continued until a total dose of 4 to 5 Gm. had been given. In most cases of kala-azar, ten injections of 150 mg. of Stilbamidine are sufficient for cure. Exceptionally, even in kala-azar,[5] larger doses have been necessary. Pentamidine was given every other day in intramuscular injections of 100 mg. dissolved in 5 cc. of distilled water. The total dosage given varied between 2 and 3 Gm.

Table 1 illustrates the diet poor in animal protein as prescribed. Theoretically the diet of these patients should consist mainly of milk, cheese, wheat, wheat gluten and corn. However, practical application renders dietary concessions necessary.

The literature stresses the fact that injections of Stilbamidine are often followed by a fall in blood pressure which on occasion may lead to sweating, dizziness, nausea and even collapse. For this reason it has been advised that 0.25 cc. of a 1 in 2,000 solution of epinephrine be injected subcutaneously ten minutes before the injection of Stilbamidine.[6] In patients with myeloma the injections of epinephrine caused more complaints than the injections of Stilbamidine! To a few patients, when sweating and dizziness were noticed after the injection, 1/150 to 1/200 grain (0.43 to 0.33 mg.) of atropine sulfate was given before the Stilbamidine with good results. Many patients notice a sensation of formication immediately after the injection.

One late sign of intoxication, dissociated anesthesia in the area supplied by the trigeminal nerve, may occur several months after the treatment.[6] This is accompanied with loss of sensation to light touch, whereas the sensations of pain, temperature and pressure are usually preserved. This facial anesthesia begins two and one-half to five months after the treatment has ended. It lasts one or more months but has a tendency to spontaneous recovery. My colleagues and I have observed this dissociated anesthesia in 4 of 20 patients treated with Stilbamidine. It may well be advisable to

protect these patients from sunlight during and after the treatment.

In patients with renal failure the drug has to be given with great caution.

RESULTS

Fifteen patients with multiple myeloma have been treated to date with injections of Stilbamidine or Pentamidine combined with a diet low in animal protein. Eleven patients were treated with Stilbamidine alone, and 1 patient with Pentamidine alone. In 1 patient Stilbamidine did not influence the pain, but a highly satisfactory result was obtained when Pentamidine was given instead of Stilbamidine. For 2 patients Pentamidine was ineffective, but the pain disappeared after treatment with Stilbamidine. For the time being, therefore, both compounds seem to have a place in the treatment of multiple myeloma, although as a rule Stilbamidine is the more effective preparation.

TABLE 1.—*Diet Poor in Animal Protein*

Tuesday

Carbohydrate 171; protein 64; fat 60; 1,480 calories

Breakfast	Dinner	Supper
1 orange	1 cup cream potato soup	½ cup vegetable soup
½ cup maltex	2 oz meat loaf	½ cup spaghetti creole
1 boiled egg	½ cup mashed potato	½ cup peas
1 slice toast	½ cup beets	2 slices bread
1 teaspoon butter	1 baked custard	2 teaspoons butter
1 cup coffee	1 slice bread	8 oz milk
1 teaspoon sugar	1 teaspoon butter	1 slice watermelon
1 oz (28 3 Gm) milk	8 oz (227 Gm) milk	

Wednesday

Carbohydrate 161, protein 76; fat 78; 1,650 calories

Breakfast	Dinner	Supper
3 prunes	1 cup tomato bouillon	1 cup cream celery soup
½ cup farina	2 oz (57 Gm) beef stew	1 hard cooked egg
1 boiled egg	1 lettuce heart	2 oz cottage cheese
1 slice toast	1 slice bread	1 baked potato
1 cup coffee	1 teaspoon butter	1 serving lettuce and tomato
1 oz milk	8 oz milk	1 blueberry muffin
1 teaspoon sugar	1 serving ice cream	1 teaspoon butter
1 teaspoon butter		1 teaspoon sugar
		1 slice bread
		8 oz milk

Thursday

Carbohydrate 236; protein 69; fat 65; 1,805 calories

Breakfast	Dinner	Supper
½ cup applesauce	1 cup vegetable soup	1 cup consomme
1 cup dry cereal	2 oz pot roast	½ cup string beans
1 boiled egg	½ cup mashed potato	1 steamed potato in jacket
1 slice toast	½ cup peas	½ cup carrots
1 teaspoon butter	3 fresh plums	½ cup beet salad
1 cup coffee	1 slice bread	2 slices bread
1 oz milk	1 teaspoon butter	2 teaspoons butter
1 teaspoon sugar	8 oz milk	8 oz milk
		1 plain cake

Friday

Carbohydrate 213, protein 87; fat 116, 2,224 calories

Breakfast	Dinner	Supper
3 prunes	1 cup cream tomato soup	1 cup cream spinach soup
½ cup farina	2 oz boiled fish	2 eggs
1 boiled egg	1 steamed potato in jacket	2 teaspoons mayonnaise
1 slice toast	½ cup peas	1 oz cottage cheese
1 teaspoon butter	1 slice bread	1 baked potato
1 oz milk	1 teaspoon butter	1 green salad
1 cup coffee	8 oz milk	2 slices bread
1 teaspoon sugar	1 serving ice cream	2 teaspoons butter
		8 oz milk
		2 oatmeal cookies

All these patients were suffering excruciating pains when the treatment was begun. Thirteen were immobilized in bed. All 15 improved considerably as far as the pain itself was concerned. Eleven could walk at the time of discharge from the hospital. One patient had paraplegia due to compression of the cord by myeloma before treatment was begun. The pains in the upper part of the body disappeared during the treatment but, as was to be expected, the mobility of the legs did not return. In 1 patient who, one month after termination of treatment, was able to walk around freely and practically without pain, diabetic coma suddenly developed and proved fatal. Two other patients died, 1 of uremia due to myeloma of the kidneys and 1 of thrombopenia. In both the pains had disappeared

Table 2 shows the quantities of Stilbamidine and Pentamidine given in the first 12 cases.

In 3 of the 15 cases the possible influence of roentgenologic treatment requires discussion. One patient had been treated unsuccessfully with small doses of roentgen irradiation (1,200 r) immediately before the treatment with Stilbamidine was begun. In the second case there was a transverse lesion of the spinal cord; the vertebral column was irradiated during the treatment with Stilbamidine. A third patient had been treated without success with large doses of roentgen irradiation (2,400 and 3,000 r) eight months before admission to the Mount Sinai Hospital. Here she became completely free of pain after treatment with Stilbamidine. Thereupon small doses of roentgen irradiation (1,200 r) were given in the hope that recalcification would be stimulated. The other patients did not receive roentgen irradiation during or after the treatment with diamidine compounds. During the treatment with Stilbamidine morphologic changes develop in the myeloma cells,[7] consisting of precipitates of ribose nucleic acid. The possibility has to be considered that these changes in the nucleoprotein of the cytoplasm of the myeloma cells may render these cells more vulnerable to roentgen rays.

The remarkable clinical improvement has persisted in 1 case for [illegible] Another patient who after treatmen[illegible] was entirely free of symptoms had a relapse sixteen months after the first treatment. Subsequent treatment with Pentamidine was ineffective, but the pains disappeared after renewed treatment with Stilbamidine. In 1 other case the improvement has now lasted for eight months. In other patients relapses of pain have occurred which usually could be treated successfully with a new series of Stilbamidine injections.

Of the 15 patients treated, 2 had Bence-Jones proteinuria with hyperglobulinemia, 4 had Bence-Jones proteinuria without hyperglobulinemia, 4 had hyperglobulinemia without Bence-Jones proteinuria and 5 had neither Bence-Jones proteinuria nor hyperglobulinemia.

The diagnosis of multiple myeloma in these cases was definitely established by punctures of the sternal marrow and biopsies. All subsequent examinations of the marrow proved that even during the period of great improvement and subjective well-being large numbers of myeloma cells were still present. As was mentioned before, the myeloma cells of the patients treated with Stilbamidine showed specific changes;[7] nevertheless the number of these cells did not decrease significantly. In the urine of patients who excreted Bence-Jones protein this abnormal substance persisted. The abnormally large globulin content of the serum also remained during the period of improvement. The treatment evidently at best only checks the disease temporarily and does not cure it.

The following 3 reports of cases illustrate the results which sometimes can be obtained with this treatment.

---

[7] (a) Snapper, I: J. Mt. Sinai Hosp 14: 119, 1946 (b) Snapper, I, and Schneid, B Blood, J. Hematol. 1: 534, 1946.

REPORT OF CASES

Case 1.—J. G., a man 59 years old, was admitted to the Mount Sinai Hospital on January 23, 1945, because of pains in the back radiating to both legs and feet. In the course of the previous year the patient had lost 35 pounds (15.9 Kg.). The pain had been progressive and for several months had disturbed his sleep. He had been admitted previously to two other hospitals, but the pains had become steadily worse.

On admission the patient could move only with difficulty in bed; he complained continuously of pain. Physical examination showed considerable tenderness of the bones and enlargement of the liver and the spleen.

The hemoglobin was 50 per cent. There were 8,800 white blood cells with a normal differential count. The sedimentation rate was 135 mm. per hour (Westergren method). The urine did not contain Bence-Jones protein. The blood serum contained 10.3 mg. of calcium per hundred cubic centimeters, 5.3 mg. of inorganic phosphorus and 16 King-Armstrong units of phosphatase. The total proteins in the serum were 6.5 Gm. per hundred cubic centimeters, with 3.8 Gm. of albumin and 2.7 Gm. of globulin. The formaldehyde gel reaction was negative.

On roentgenologic examination numerous small areas of rarefaction were seen throughout the calvarium. There were many osteophytes in the spine. The pedicles of the thoracic vertebrae were poorly outlined due to osteoporosis. In the pelvis many areas of rarefaction were seen. There was a large, gaping, incomplete fracture of the head of the right femur.

Sternal marrow aspiration showed 52 per cent plasma cells.

Between February 7 and February 23 the patient received six treatments of 200 r each to the lumbar spine and six treatments of 200 r to the sacrum. This treatment had no effect on the pains.

Between February 18 and March 20 nineteen intravenous injections of Stilbamidine were given, totaling 2,500 mg. The first decrease in the pain was noticed about the middle of March, after twelve injections had been given. Thereafter the improvement advanced rapidly. At his discharge, on April 4, the patient walked out of the hospital almost like a normal man. Shortly afterwards he resumed his activities as a porter, and he has been working until now (October 1946) without interruption. His general condition is excellent. He is far stronger than the average person; he currently carries heavy loads on his shoulders and shifts weighty burdens without difficulty.

In this patient the disease is evidently arrested. Repeated roentgenologic examinations reveal that none of the osteolytic areas demonstrated in February 1945 have enlarged to date (May 1946). Most of the areas of decalcification—for instance, those in the skull—have remained unchanged. There are signs of healing in some of the diseased areas of the skeletal system. The large defect at the head of the right femur has practically disappeared. The arrest of the disease is also demonstrated by the fact that none of the vertebrae has collapsed, despite the heavy work the man is doing.

Although this man is free from symptoms and has regained 35 pounds, at best the disease was only arrested, because in May 1945, when he felt entirely well, the bone marrow still contained many myeloma cells. The sedimentation rate of the red blood cells has remained high (81 mm. per hour in March 1946).

Case 2.—Mrs. E. W., 61 years of age, had been suffering from severe pain in the lower part of the back beginning in March 1944. Since May she had been unable to walk and had a great deal of pain even when turning in bed. Between October and December she was in another hospital, where she was confined to bed. At that time roentgenologic examination showed only a moderate degree of osteoporosis. The condition was rapidly progressive, and in February 1945 the patient was admitted to the Mount Sinai Hospital. At this time she could hardly move in bed because of pain on slightest motion. Even slight shaking of the bed caused severe pain.

Table 2.—*Results of Treatment of Twelve Patients Having Myeloma With Stilbamidine and Pentamidine*

	Treatment with Stilbamidine		Total Dosage, Mg.	Bence-Jones Protein in Urine	Globulin in Serum, Gm. in Each 100 Cc.	Total Protein in Serum, Gm. in Each 100 Cc.	Formaldehyde Reaction	Results
	Started	Finished

S C	6/21/46*	8/ 4/46*	2,200	—	4.1	7.4	+	Excellent result with pentamidine

* On these dates treatment was with pentamidine.

The hemoglobin was 65 per cent. There were 10,200 white blood cells with a normal differential count. The sedimentation rate of the red blood cells was first increased (18 mm. in thirty-seven minutes, Linzenmeyer method) but was later found to be normal (18 mm. in sixty-one minutes) even before the treatment with Stilbamidine was started. During the entire observation, the sedimentation rate has remained normal.

The urine did not contain Bence-Jones protein. The blood serum contained 12 mg. of calcium per hundred cubic centimeters, 4 mg. of inorganic phosphorus and 9 King-Armstrong units of phosphatase. The total proteins in the serum were 6.2 Gm. per hundred cubic centimeters, with 4.6 Gm. of albumin and 1.6 Gm. of globulin. The formaldehyde gel reaction was negative.

Comparison of roentgenograms made in March 1945 with roentgenograms made in October 1944 revealed that the disease had progressed rapidly. The skull now contained numerous small areas of bone destruction. There were several pathologic fractures in the pelvis. Many new osteolytic areas had developed in the arms and legs. Puncture of the sternal marrow and sternal biopsy confirmed the diagnosis of multiple myeloma.

A course of Stilbamidine was given between April 17 and May 17, 1945, totaling 1,175 mg. A second series was given between June 15 and July 9, totaling 1,100 mg. Shortly after the beginning of May the patient could sit up in bed without help. In August, after the second series had been terminated, she returned home, where she resumed her usual activities as a housewife. In August anesthesia of the forehead developed. This gradually spread to the cheeks and the lips, but after a few months it started to recede.

When the patient was readmitted for a new check-up in February 1946, some numbness in the distribution of the second branch of the trigeminal nerve still persisted. Roentgenologic examination showed that none of the osteolytic areas had increased in size. The fractures of the pelvis had healed, and there was considerable recalcification and reconstruction of bone in the upper part of both femurs and in the humeri. In April a third series of injections of Stilbamidine was given, totaling 1,225 mg. In this patient also, clinical recovery only had been achieved. In March aspiration of the iliac crest still revealed the presence of 30 per cent myeloma cells in the bone marrow: evidently the disease had only been arrested, not cured.

At the end of July 1946 a relapse of the multiple myeloma set in, which is now being controlled again by a new series of injections of Stilbamidine.

Case 3.—Mrs. K. B., 47 years old, was admitted with the following history: In August 1944 a lower right molar tooth was extracted and a cyst of the jaw removed. In September she noticed the onset of dull gnawing pain in the right thigh. After November, pain in the lower ribs and in the back developed. The pain became progressively worse, so that in September 1945 she was unable to walk without a stick. She was admitted to another hospital, where a diagnosis of multiple myeloma was made. She then received roentgen treatment (2,400 r and 3,000 r) to the right side of the pelvis and to the right hip without relief of pain. The second series of roentgen treatments was finished in September.

In March 1946 she was transferred to the Mount Sinai Hospital. On admission she could not move in bed without pain. When she tried to lift her head from the pillow she suffered excruciating pains. The skeleton was tender on pressure. The mobility of the right hip was much impaired, and abduction of the right leg was greatly limited.

Hemoglobin was 85 per cent. There were 5,200 white blood cells with 3 per cent plasma cells. With this exception the differential count was normal. The sedimentation rate was 20 mm. per hour (Westergren method). The urine contained a moderate amount of Bence-Jones protein. The blood serum contained 11.1 mg. of calcium per hundred cubic centimeters, 2.5 mg. of inorganic phosphate and 7 King-Armstrong units of phosphatase. The total proteins in the serum were 7.5 Gm. per hundred cubic centimeters, with 4.3 Gm. of albumin and 3.2 Gm of globulin. The formaldehyde gel reaction was negative.

Roentgenologic examination of skull, long bones, chest and spine showed numerous destructive lesions. Most of the lesions were small, but large osteolytic areas were seen in the right frontal bone, the left radius and both femurs. A large osteolytic area had destroyed about 50 per cent of the head and the neck of the right femur.

Puncture of the sternal marrow showed the presence of numerous plasma cells.

Between April 5 and May 6 seventeen intravenous injections of Stilbamidine were given, totaling 2,250 mg. On April 8, after three injections had been given, the patient noticed pronounced improvement. The pain in the back had diminished so that now she could lift her head without difficulty. On April 15, after 900 mg. of Stilbamidine had been given, the patient stated that "she was incomparably improved." She was now able to sit up in bed unaided without pain in the back or the right hip. After April 25 she was put in a wheelchair daily, where she could sit without discomfort. On May 4 the patient felt rather well. On standing or after sitting in a chair for a long time she noticed some weakness of the muscles of the hips and the thighs, but did not feel pain. The mobility in the right hip was now practically normal.

New roentgenograms of the head of the right femur showed no change in the large destructive lesion. The patient was therefore not permitted to walk. It was decided at this time to give additional roentgen treatment. The pains due to the myelomatous disease were halted by the treatment with Stilbamidine, but it was hoped that roentgen irradiation might now bring about recalcification.

However, even after this course of irradiation no pronounced evidence of recalcification could be found.

The treatment with Stilbamidine was terminated June 4; by this time a total of 3,450 mg. had been given. The patient now walked about freely and painlessly. Only with difficulty could she be persuaded to use a cane. In December, nearly eight months after the termination of treatment, the patient was in excellent general condition and continued to walk around freely. At this time the sedimentation rate of the red blood cells had become completely normal, 5 mm. per hour. The total blood count showed normal values.

COMMENT

For all 15 patients with multiple myeloma treated with Stilbamidine or Pentamidine and kept on a diet low in animal protein, considerable improvement was obtained. These substances evidently have a specific influence on the disease, as is evidenced by the rapid alleviation of pain after the treatment has been instituted. The disease is, however, not cured but is temporarily checked in its development. The latter result can be obtained even in cases in which the disease has been rapidly progressive before the treatment is started.

A word of caution is in order. The disappearance of the pain may lead to premature mobilization of these patients. Despite the alleviation of pain, resulting from the treatment with Stilbamidine, the skeleton is still intensely diseased. Mobilization should therefore be gradual in order to prevent new fractures.

It is pertinent to inquire why the pains disappear although the disease persists. It may be assumed that Stilbamidine, and sometimes also Pentamidine, is capable of arresting proliferation of the myeloma cells because in the cases reported the osteolytic lesions have not expanded for some time after the cessation of treatment with Stilbamidine. There are other conditions in which arrest of abnormal proliferation in bone is accompanied by disappearance of pain even if the disease of the bone persists. In patients with Recklinghausen's disease of the bone, removal of the parathyroid adenoma often relieves the pain in the bone within two days after the operation. At this time the bone is still intensely diseased but the progressive erosion by osteoclastic proliferation is arrested. Analogous conditions may well exist in patients with mammary cancer and skeletal metastases in whom testosterone treatment occasionally relieves the pain. In these cases the carcinomatous deposits in the bone do not disappear but for some time the proliferation is halted. During this period the pain is much relieved. It is therefore possible that arrest of proliferation of the myeloma cells explains the improvement observed in patients treated with Stilbamidine and Pentamidine.

The arresting influence which Stilbamidine seems to exercise on the development of multiple myeloma may well be connected with observations recently reported by Kopac.[8] He found that in tissue cultures Stilbamidine destroys neoplastic cells of transplantable animal tumors without damaging the normal cells. The shape of the nuclei of tumor cells changed under the influence of Stilbamidine, and mitosis of the tumor cells was stopped. Kopac is of the opinion that Stilbamidine has a chemical influence on certain specific nucleoproteins of the nuclei. In the series reported here no change of the nucleoprotein of the nuclei of the myeloma cells could be observed. However, as mentioned earlier, in

---

[8] Kopac, M. J.: Tr. New York Acad. Sc. 8: 5, 1945.

10 of 13 patients with myeloma treated with Stilbamidine, specific changes of the nucleoprotein of the cytoplasm, that is, of the ribonucleic acid, occurred.[7] Until now these changes of the cytoplasm of the myeloma cells have not been found after treatment with Pentamidine.

SUMMARY

A series of fifteen or more intravenous injections of 150 mg. of Stilbamidine (4,4-diamidinostilbene), combined with a diet low in animal protein, relieves the pain in most cases of multiple myeloma. For 1 patient the same result was obtained by intramuscular administration of 100 mg. of Pentamidine (4,4′-[pentamethylenedioxy] dibenzamidine). These compounds do not contain antimony. In 1 patient Stilbamidine had no result but Pentamidine relieved the pain. However, the reverse was true in 2 other cases in which Pentamidine seemed to be ineffective but the pain disappeared after treatment with Stilbamidine. Satisfactory even if temporary results have been obtained for all 15 patients with myeloma treated up to the present time.

Improvement starts soon after the inception of the treatment, often beginning after the third or fourth injection. No results have been obtained when the treatment has been accompanied by a diet high in protein.

Fifteen patients have been treated to date. In all cases the pain was favorably influenced. Relapses did occur. Eleven patients were able to walk at the time of discharge from the hospital. One of these died later of diabetic coma. One patient had paraplegia before the treatment was started, and 2 other patients died of myeloma of the kidney and thrombopenia, respectively.

The treatment merely checks the disease and does not cure it. Even when the patients feel completely well, myeloma cells can still be found in the bone marrow and Bence-Jones proteinuria and hyperglobulinemia persist.

During treatment with Stilbamidine specific morphologic changes develop in the cytoplasm of the myeloma cells, consisting of precipitates of ribonucleic acid.

Immunization Against Influenza.—Reactions to influenza vaccine correspond in severity and character to reactions following typhoid vaccine. They are primarily attributable to the virus content. In the studies referred to, about half of the vaccinated individuals had some complaints and about 1 to 2 per cent developed febrile reactions up to 101.5 F. within twenty-four hours of inoculation. Such symptoms usually last no longer than a day. At the site of inoculation, edema, redness and tenderness may develop in about twelve hours and persist for about a day or slightly longer. The local and systemic symptoms are related to the quantity of virus administered rather than to any nonvirus impurities that are present. One word of caution is warranted, and that is the danger of anaphylactic reactions in persons with known egg sensitivity who are given any vaccine of egg origin. The development of sensitivity to repeated inoculations seems to be less of a risk or no risk at all. An adult who has once been given an injection of vaccine originating from an egg, and this includes a good number of vaccines, is much less likely to have an acute reaction than one who is to have his first inoculation. . . . On the basis of the results of these studies carried out by the Commission on Influenza, the Surgeon General directed that plans be made to vaccinate the entire army in the fall of 1945, using vaccine prepared in the same manner as that employed in the field studies. For the first time development of mass production as well as mass immunization with influenza vaccine was involved and was accomplished successfully.—Salk, Jonas E., and Francis, Thomas, Jr.: Immunization Against Influenza, *Annals of Internal Medicine,* September 1946.

PNEUMONIA FOLLOWING NONPENETRATING PULMONARY INJURIES

EDWARD PHILLIPS, M.D.
Oakland, Calif.

"Post-traumatic pneumonia" is a loose term which has been used to describe pneumonia following chest injury, pneumonia following trauma to the body generally,[1] and pneumonia complicating penetrating chest wounds.[2] The phrase post-traumatic pneumonia is used in this paper to indicate the types of pneumonia which follow trauma to the chest. Cases of penetrating wounds are not included because pneumonitis in such cases is usually due to direct contamination.

This report is based on observations made on 73 adult patients with post-traumatic pneumonia treated in this hospital. Every patient had an acute febrile illness with signs and symptoms of pneumonia confirmed by roentgenograms. Patients who were unconscious or who received a general anesthetic are not included in this study. Patients who had emesis were excluded, as were patients with possible aspiration or hypostatic pneumonia. All patients in whom pneumonia developed one week subsequent to their injury were ambulatory, and the cases are reported later.

Twenty-eight patients with post-traumatic pneumonia had an intact thorax; 43 patients had fractured ribs, 1 had a fractured scapula and 1 had a fractured sternum.

Three patients died with a resultant mortality rate of 4.1 per cent.

INCIDENCE

Moritz [3] and Blumer,[4] quoting the German literature, have stated that 0.13 to 4.4 per cent of pneumonia is due to trauma.

In this hospital 73 of 3,170 cases of all types of primary pneumonia were due to trauma, the incidence of post-traumatic pneumonia being 2.3 per cent.

The incidence as to age and sex was similar to that reported from this hospital for primary pneumococcic pneumonia.[5]

PATHOGENESIS OF POST-TRAUMATIC PNEUMONIA

It has long been known that pneumonia may follow simple contusion of the chest wall. Frequently such cases have been regarded with skepticism, since one could not be certain that the patient did not have pneumonia before the injury or that the pneumonia and the injury were not coincidental.[3] As more cases were collected, and as the knowledge of the pathogenesis of pneumonia increased, trauma to the chest has been accepted as an etiologic factor in pneumonia.[6] Austrian [7]

and Shipley,[8] in recent articles, expressed the opinion that there was some doubt that trauma could be an etiologic factor in pneumonia. Shipley stated that "most pathologists and bacteriologists look askance at trauma as an etiologic factor in pneumonia." However, the work of de Takats and his associates,[9] Robertson,[6a] and Coryllos and Birnbaum[10] has made the pathogenesis of post-traumatic pneumonia clear.

Until the work of de Takats, Fenn and Jenkinson[9] appeared, a rational explanation of the pathogenesis of post-traumatic pneumonia in cases without definite clinical evidence of pulmonary contusion was lacking. Blumer[4] thought that the injury probably lowered resistance to infection. Schiff[11] thought that post-traumatic pneumonia was due to vagal stimulation which produced vasodilatation in the pulmonary field.

De Takats, Fenn and Jenkinson[9] demonstrated by animal experiments that blunt injury to the wall of the chest with or without fracture of the ribs produced a spasm of the bronchial tree and bronchial hypersecretion which resulted in pulmonary atelectasis. Bilateral sectioning of the vagi or a sufficient dose of atropine prevented the occurrence of this chain of events. This proved that atelectasis following trauma to the chest was due to a vagal reflex. These authors also cited clinical cases which supported their experimental work. Coryllos and Birnbaum[10] showed that unrelieved atelectasis is followed by pneumonia. Robertson's[6a] experiments proved that local pulmonary irritation or injury is an important factor in the pathogenesis of pneumonia. Pulmonary injury and/or atelectasis is frequently present in patients with nonpenetrating pulmonary injuries.[12]

Moritz[3] stated that the pathology of post-traumatic pneumonia did not differ from that of lobar pneumonia.

PATHOGENESIS AND PATHOLOGY OF PREDISPOSING PULMONARY LESIONS

It has long been known that extensive pulmonary injury may follow trauma which may not mark or damage the thoracic wall. Fallon[6b] stated that Morgagni first described such pulmonary lesions in 1761. Reports of cases have appeared sporadically in the English literature since 1840.

The work of Zuckerman[13] and of Williams[14] established that pressure applied suddenly to the thorax was capable of producing pulmonary injury without damaging the thoracic wall. Any sudden pressure on the thorax in excess of 2½ to 7½ pounds per square inch may result in pulmonary damage, and if the pressure has been applied only momentarily the thorax may not be marked. This is due to the elasticity of the thorax. It has been demonstrated that the sternum of cadavers may be compressed to the vertebral column without fracturing the ribs.[3]

Osborn[15] has calculated that the pressure sustained on the thorax in automobile accidents may greatly exceed 7 pounds per square inch. In 2 of his cases, pressures far in excess of 7 pounds per square inch had been applied to the thorax for $\frac{1}{30}$ and $\frac{1}{45}$ of a second, respectively. These cases were without fractures or marks on the thorax.

Zuckerman[13] proved in blast injuries that it is the sudden compression of the wall of the chest which contuses the underlying lung. This has been confirmed by Williams,[14] Wilson and Tunbridge[16] and Osborn[15] as the mechanism of pulmonary injury regardless of the source of the force.[17]

Klubs[11] showed in animal experiments that blows delivered to the anterior and lateral aspects of the chest caused more extensive and more numerous injuries to the underlying lung than did blows delivered posteriorly. This is so because the posterior thoracic wall is relatively rigid and thick and is not compressed readily. It is interesting to note that I have not observed a single case of pulmonary injury following strictly posterior blows.

The common causes of lung injuries in the intact thorax are falls from various distances, blows on the chest by flying or falling objects, auto and aviation accidents and "blast."[18] My experience has been similar except that it has not included aviation accidents or "blast" injuries.

There are three types of pulmonary injuries:[15] those due to direct violence, to contrecoup and to "pincer" forces in V-shaped spaces. Lung injuries due to direct violence may show rib markings. These are well seen in children and in animals. The lesion occurring most commonly after direct violence is contusion of the parietal pleura.[19] Klubs[11] also showed that fibrinous pleuritis was common over the affected lobe and demonstrated fine pleural adhesions over the contused areas as early as nine hours after injury. In direct trauma, the lung below the incoming ribs will show varying degrees of subpleural ecchymosis or hematoma and hemorrhagic consolidation of the underlying lung. The latter is due to rupture of the alveolar capillaries.

The typical contrecoup lesion is posterior because the chest is fixed posteriorly and the thorax is compressed from the front and sides. Osborn[15] has elucidated the pathology of these lesions, and this description is based on his work: The earliest contrecoup lesion is a hemorrhagic straight line almost constantly corresponding to the angles of the ribs. This line is often 1 cm. wide and 20 cm. long and usually does not reach to the extreme base but may extend posteriorly to the cupula pleurae. This lesion may be missed easily at autopsy. In addition to the hemorrhagic line, a row of tiny blisters may be present. The hemorrhagic line is due to subpleural hemorrhage and hemorrhagic contusion of the underlying alveoli. Contrecoup lesions may be massive and may endanger life. The lesion may be on the side opposite the direct blow. Extensive contrecoup lesions show hemorrhagic consolidation from the angle of the ribs laterally and anteriorly and may blend with the direct lesion.

The third type of lesion due to "pincer" forces in V-shaped spaces was first described by Osborn[20] in 1940. The V-shaped spaces in the thorax are the costophrenic angles and the posterior part of the right middle lobe. In these spaces pincer forces may be applied to the sides of the V, thus contusing the struc-

tures in the V-space. The contusion in the costophrenic angle is caused by nipping of the lung between the lateral wall of the chest and the spleen or the liver. The posterior part of the middle lobe of the right lung is apt to be nipped between the upper and the lower lobe.

Cavity formation is common in extensive contusions.[15] These are usually seen at the bases. Their walls are smooth and are formed of hard blood clot. Wilson and Tunbridge [16] have described such cavitations in blast injuries. Fallon [6b] reported the case of a 24 year old medical student in whom there developed a hemorrhagic cavity in the lower lobe of the left lung following a blow on the chest sustained while boxing.

Hass [18a] has stated that the subpleural blebs (Osborn's "blisters") are common in aircraft accidents. The blebs are thin walled and occasionally rupture to produce pneumothorax. Deep seated emphysema may also be present, especially in the lower lobes, where the emphysematous areas appear as multiple spherical air-bearing spaces from 2 to 5 mm. in diameter.

PULMONARY INJURIES ASSOCIATED WITH POST-TRAUMATIC PNEUMONIA

In the past three years, 44 adult patients with pulmonary injury with intact thorax have been observed in this hospital. In 4 of these patients with previously normal lungs pneumothorax developed following trauma to the chest, and in 1 of these pneumonia developed. Pneumothorax in the intact thorax following trauma to normal lungs is not as infrequent as the German literature indicates.[19a] Washburn [21] cited such a case and found similar ones in the literature. Roberts and Tubbs [22] reported 3 cases recently.

One patient with hemopneumothorax and 2 patients with hemothorax with intact chest walls were instances of secondary hemothorax. Secondary hemothorax occurs eight to twenty-one days after the injury [19a] and is presumably caused by a rupture of a subpleural hematoma. The patient with hemopneumothorax was an elderly man with a long standing asthma. Pneumonia did not develop in these patients.

Thirteen cases of pulmonary contusion were diagnosed on the basis of hemoptysis and clinical and/or roentgenologic signs of consolidation. In 6 of these patients there later developed pneumonia (table 1). Three additional cases of unsuspected pulmonary contusion with intact thorax were found at autopsy.

Twenty-one patients in whom pneumonia developed after chest injuries without fractures are presumed to have sustained pulmonary injury and/or atelectasis. The rationale for including such cases is based on the work of de Takats and his co-workers cited previously.

Fractures of the thorax are recognized readily but may be missed in cases in which the thorax is not marked. Pulmonary injuries in patients with fractures of the thorax are similar to those already described. In addition, puncture of the lung or its laceration by bone fragments may be present. Seventy-six instances of pulmonary injuries associated with fractures of the chest wall were observed.

Pneumothorax in the presence of fractured ribs usually is presumed to be due to laceration of the lung by a rib fragment but may be due to rupture of a subpleural bleb.[18a] Four cases of pneumothorax were observed. One patient had a tension pneumothorax and subcutaneous emphysema. The presence of subcutaneous emphysema presupposes a laceration in the parietal pleura as well as in the lung.[6c] The patient with tension pneumothorax died fifty hours after the injury. An extensively contused right lung with two small tears in the visceral pleura and a laceration in the parietal pleura were found at autopsy. In 2 other patients with pneumothorax traumatic pneumonia developed (table 1).

Hemopneumothorax must be due to laceration of the lung.[6c] Six such cases were seen. One patient had a stove-in chest, a tension pneumothorax, hemothorax and subcutaneous emphysema; in spite of a complicating pneumonia the patient recovered. In 3 patients pneumonia developed; a fatal case is reported later (case 14). Only one instance of secondary hemopneumothorax was observed in patients with fractured ribs.

Laceration of the lung is followed by slight bleeding which seldom menaces life.[23] Extensive intrathoracic hemorrhage may follow laceration of an intercostal or internal mammary vessel or a vascularized adhesion.[8] Fourteen cases of hemothorax were seen with fractured ribs. One case of secondary hemothorax followed fracture of the clavicle. Three additional cases of secondary hemothorax followed fracture of the ribs. The longest period between injury and the development of hemothorax was twenty-six days.

No obvious lesion	21	27
Totals	28	45

When the hemothorax is small it is usually assumed that the bleeding is from a lacerated lung, but the bleeding may be from the parietes. A case of hemothorax due to laceration of the parietal pleura, proved at autopsy, is reported later (case 12).

Six patients with hemothorax also had subcutaneous emphysema, but intrapleural air could not be demonstrated.

In 6 fatal cases of hemothorax wherein death was due to trauma and not to pneumonia, 4 patients had gross laceration of the lung by rib fragments. Two of these patients had a stove-in chest and extensive pulmonary contusion. Three cases of fractured ribs and hemothorax were not recognized ante mortem because extensive injuries of the head or extremities drew attention away from the chest, which was unmarked in each instance.

One patient with hemothorax and fractures of the sternum and third rib on the left side also displayed widening of the mediastinum by roentgenologic examination. After twelve days the mediastinal shadow was normal. This was assumed to have been a mediastinal hemorrhage.

In 4 of the 18 patients with hemothorax, pneumonia developed (table 1). The other surviving patients ran a temperature up to 101 F. until the blood was absorbed or evacuated from the pleural cavity.

23. Moritz.[3] Parker.[7c]

Eighteen patients with pulmonary contusion and/or laceration without obvious hemothorax and with rib fractures were treated. The diagnosis was made on the basis of hemoptysis and/or signs of pulmonary consolidation in the absence of evidence of pulmonary infection. Six of these patients subsequently had pneumonia (table 1).

TABLE 2.—*Temporal Relationship of Pneumonia to Injury*

Days from Injury to Onset of Pneumonia	Patients with Intact Thorax		Patients with Fracture of Thorax

Totals	28	100.0	45	100.0

Five patients with fractured ribs had subcutaneous emphysema without other clinical or roentgenologic evidence of pulmonary injury. In 2 of these patients pneumonia developed later. Only 1 patient had preexisting pulmonary disease, namely, pulmonary emphysema with large bilateral bullae. A patient with mediastinal and subcutaneous emphysema contracted pneumonia (table 1).

Twenty-seven patients with thoracic fractures did not have definite evidence of pulmonary injury until pneumonia developed. The reasons for including these cases in this report have been discussed previously.

The diagnosis of pulmonary injury is frequently missed. Osborn[16] and Hass[18a] cited cases in which the symptoms were erroneously ascribed to shock or head injury. Dean, Thomas and Allison[24] stated that physical signs of pulmonary injury may be present although the patient lacks symptoms referable to the respiratory system. The diagnosis must first be suspected and then confirmed. Symptoms of shock, anxiety, restlessness, dyspnea and cyanosis may be due to pulmonary injury.[25] The presence of hemoptysis or of any abnormality in the chest should suggest the diagnosis. Unfortunately, it is a frequent practice in cases of contusion of the chest and fractured ribs to strap the chest without examining the lungs.

* Sputum in 1 case also contained a few type IV pneumococci.

Every case suggestive of injury to the chest should have frequent, careful physical and roentgenologic studies. Westermark[26] found by careful roentgenologic studies that 65 per cent of patients with chest injuries but without rib fractures had demonstrable changes in the lungs and that 86.6 per cent of those with fractured ribs had demonstrable changes in the lungs! The practice of taking spot films over areas of suspected rib fractures gives little information about the underlying lung and none about the status of the opposite lung or contrecoup injuries. Economy permitting, lateral and posterior-anterior films of the chest should be made in every case.

THE TEMPORAL RELATIONSHIP OF TRAUMA AND PNEUMONIA

The interval between trauma and the development of pneumonia is variable. Blumer[1] has stated that the general rule is to disregard trauma as a factor if pneumonia develops after six days. Shipley[8] was of the opinion that if the pneumonia comes two to three days after the injury, it may be presumed that trauma is the exciting cause. Fallon[9b] has stated that pneumonia may follow trauma by one to ten days. Stoneburner and Finland[1] and Spicer[9c] accepted some cases of pneumonia occurring more than two weeks after injury as post-traumatic. The bulk of the reported cases occurred within six days after injury. Pneumonia occurring later must be evaluated carefully.

TABLE 4.—*Relationship of Pneumonia to Site of Injury*

Site of Pneumonia	No. of Patients with Intact Thorax	No. of Patients with Fractures of Thorax
Same side as injury only	24	30
"Contrecoup" side only	1	9
Same side plus "contrecoup" side	3	6
Totals	28	45

In over 92 per cent of the patients in this series pneumonia developed within six days of the injury (table 2).

BACTERIOLOGIC OBSERVATIONS

Sputum typing was done in 56 (or 76.7 per cent) of the cases. Blood cultures were made in most instances, and pleural and empyema fluids were cultured.

Table 3 shows that there were 56 cases of pneumococcic pneumonia. (One case with sputum containing more streptococci than pneumococci is included because there were more than 11 pneumococci per oil immersion field). Of these, only 28 cases (50 per cent) reacted with specific antiserums, types I to XXXIII. In contrast, 62 per cent of the cases of primary pneumococcic pneumonia in this hospital were type-specific.[5] The small incidence of type-specific pneumococcic pneumonia is interpreted as signifying a preponderance of less virulent and higher type (XXXIV to LXXV) pneumococci in the post-traumatic cases. Indeed, the preponderance of the "higher" and less virulent types of organisms is striking. Types I, II, III, V, VII, VIII, IX and XX, which accounted for approximately 50 per cent of the typed primary pneumococcic pneumonia in this hospital,[5] were not found in the post-traumatic cases.

Only 1 case of bacteremia (type XII) was encountered.

[26] Westermark, N., cited by de Takats and others.[9]

SITE OF PNEUMONIA IN RELATION TO SITE OF TRAUMA

In 54 patients (74 per cent) pneumonia developed only on the same side as the injury. Nine patients had bilateral pneumonia, that on the contrecoup side being in the lower posterior lung field. In 10 patients pneumonia developed on the contrecoup side only (table 4).

Stoneburner and Finland[1] failed to find an instance of "contrecoup pneumonia" in 29 patients in whom pneumonia developed following injury to the chest. I am unable to account for this difference between the two series, because contrecoup traumatic pulmonary lesions are common.[12]

Pneumonia of the upper lobe followed direct injury to the upper anterior part of the chest, and in 1 case, to the scapula.

INCIDENCE OF PREVIOUS RESPIRATORY DISEASES OR INJURY TO THE LUNGS

Only 7 patients (9.6 per cent) gave a history of respiratory infection present at the time of injury. Six patients had the common cold, and 1 had asthmatic bronchitis.

Table 1 shows the existing traumatic pulmonary lesions known to be present when the pneumonia developed.

TYPE OF THERAPY BEFORE THE DEVELOPMENT OF PNEUMONIA

Table 6 shows the type of therapy used in the treatment of thoracic fractures or contusions of the chest before the onset of pneumonia. Twenty-one, or 29 per cent, of the patients had been treated by immobilization of the thorax by adhesive strapping. Three of these patients had complete circular strapping. One patient had a plaster of paris shoulder spica; 1 had a body cast. The patients who had not received previous treatment had relatively mild injuries of the chest.

CLINICAL COURSE

All 73 cases of post-traumatic pneumonia simulated mild to moderately severe primary pneumococcic pneumonia. Leukopenia and the virulent "lower" type pneumococci were not encountered. The incidence of bacteremia and multiple lobe involvement was low. Sputum counts were generally low. The sputum contained 75 or more pneumococci per oil immersion field in only 2 cases, 1 of which was fatal. The latter patient was the only one who showed definite albuminuria (case 12).

The duration of the post-traumatic pneumonia was comparable to that of primary pneumonia. Over 50 per cent of the patients recovered within one week. In 2 of the 3 fatal cases the patients had hemothorax and other complications: case 12 also involved a traumatic rupture of the pancreas, and in the other case there were multiple fractures (case 14). The third patient died after a rib resection for empyema.

Totals	28	100.0	45	100.0

COMPLICATIONS

The complications of post-traumatic pneumonia are listed in table 7. Almost all complications occurred in patients with fractured ribs.

One patient was treated inadequately elsewhere and was admitted to this hospital with empyema. He was treated unsuccessfully with intrathoracic instillations of penicillin but recovered after rib resection. The other patient with empyema died, and the case is reported later (case 13).

The incidence of pleural effusion, 5.5 per cent, is higher than that of primary pneumococcic pneumonia in this hospital.[5]

TREATMENT

1. *Prophylactic.*—Post-traumatic pneumonia can be prevented or minimized by the early treatment of all patients with injury to the chest for pulmonary atelectasis and potential infection.

De Takats and his associates[9] showed that the intravenous administration of $\frac{1}{150}$ grain (0.0004 Gm.) of atropine sulfate and $\frac{1}{2}$ grain (0.03 Gm.) papaverine hydrochloride will inhibit or break the vagal reflex which causes bronchospasm and hypersecretion. All patients with chest injury should receive such medication early in order to prevent reflex atelectasis. As much as $\frac{1}{60}$ grain (0.001 Gm.) of atropine[27] and 1$\frac{1}{2}$ grains (0.1 Gm.) of papaverine[28] can be given intravenously every four hours without untoward effect. The intravenous administration of $\frac{1}{150}$ grain (0.0004 Gm.) of atropine and of $\frac{1}{2}$ grain (0.03 Gm.) of papaverine every four hours for two days after injury will relieve bronchospasm and hypersecretion and combat atelectasis and pulmonary edema.[27] Patients who are not

[27] de Takats, G.; Beck, W. C., and Fenn, G. K.: Pulmonary Embolism: An Experimental and Clinical Study, Surgery 6: 339 (Sept.) 1939.

[28] Phillips, E., and Levine, E. B.: Unpublished data.

hospitalized may be given comparable oral doses of the drugs, although the value of such treatment is not established.

All patients hospitalized with injuries to the chest must receive large doses of penicillin or sulfadiazine early in order to prevent pneumonia. In this series pneumonia developed in 2 patients with blood sulfadiazine levels of less than 8 mg. per hundred cubic centimeters. In patients with higher sulfadiazine blood levels pneumonia did not develop. Penicillin is the drug of choice because of its efficacy and freedom from serious toxic reactions.

Twenty-six consecutive patients with severe chest and pulmonary injuries who were placed on the above regimen did not contract pneumonia or other complicating infections.

2. *Active Treatment.*—Patients with mild to moderately severe post-traumatic pneumonia responded well to penicillin therapy. Penicillin in doses of 25,000 units should be administered intramuscularly every three hours until the temperature has been normal for forty-eight to seventy-two hours.[29] The oral administration every three hours of 100,000 units of calcium penicillin combined with 2 Gm. of calcium carbonate[30] produced satisfactory therapeutic results in patients with mild pneumonia.

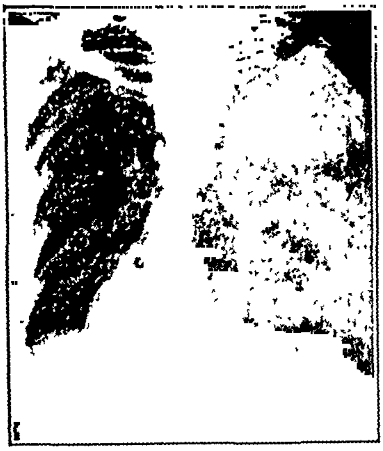

Fig. 1 (case 3).—Type IV pneumococcic pneumonia of the right lung.

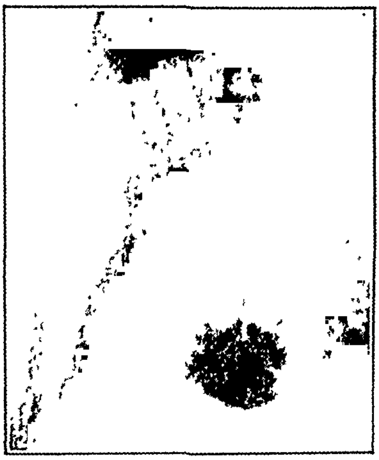

Fig. 2 (case 3).—Type IV pneumococcic pneumonia of the right lung.

Patients with severe pneumonia (although rare in the post-traumatic group) should be treated with both penicillin and sulfadiazine. Since it has been demonstrated that "double doses" of sulfadiazine resulted in a decrease in the mortality rate and a decrease in the incidence of complicating conditions without any increase in the incidence of toxic reactions,[5] 5 Gm. of sodium sulfadiazine in 500 cc. of sodium *r*-lactate one-sixth molar were given intravenously, and 5 Gm. of sulfadiazine were given orally (total 10 Gm.) as an initial dose. This was followed by 4 Gm. of sulfadiazine every six hours orally as a maintenance dose until the temperature remained normal for twenty-four hours. Adequate alkali (sodium bicarbonate, potassium bicarbonate or sodium lactate) was used routinely to keep the p_H of the urine at 7.5.

Combined penicillin-sulfadiazine therapy is indicated when there is failure to respond to penicillin alone, leukopenia, high pneumococci count in the sputum, pulmonary edema, shock, toxic delirium or other evidence of severe infection or toxicity. In such cases the dose of penicillin may also be increased up to 50,000 units every two hours.

In this series 2 of the patients who died were treated with sulfadiazine alone and probably would have been saved if penicillin had been available.

Oxygen by inhalation is indicated for cyanosis or severe dyspnea. Other adjuvant therapy such as cough mixtures, fluids and non-narcotic analgesics were used as needed.

3. *Relief of Chest Pain.*—De Takats[9] and Harmon[31] have emphasized that the treatment of fractured ribs by adhesive strapping is unphysiologic. The use of strapping or of other procedures which cause hypoventilation should be abandoned. Complete circular strapping is never justified.[22] Harmon, Baker and Kornegay[31] have demonstrated that the injection of local anesthetic drugs at the fracture sites relieves pain, enables the patient to cough with relative comfort and increases his vital capacity. These workers inject each fracture site with 2 to 6 cc. of a solution containing 0.5 per cent procaine hydrochloride and 0.1 per cent Eucupine dihydrochloride. (Eucupine is isoamylhydrocupreine.) Sedatives and depressant analgesics are unnecessary except in the treatment of delirium. In such cases meperidine hydrochloride (Demerol hydrochloride) should be used in preference to morphine or codeine to avoid respiratory depression. Relief of pleuritic pain can be obtained by cutaneous anesthesia with ethyl chloride spray or procaine injections as recommended by Dybdahl.[32] In my experience these measures have proved highly efficacious.

4. *General Measures.*—Patients with pulmonary and chest injuries should be given little, if any, sedatives in order to preserve the cough reflex. Oxygen by inhalation is indicated for cyanosis and dyspnea. Deep breathing exercises or carbon dioxide whiffs may be used for hyperventilation. Expectorants, such as ammonium chloride and saturated solution of potassium iodide to attenuate bronchial secretions, should be given to all patients with thick or tenacious mucus and probably should be used routinely. Frequent movement of bed patients and early ambulation is essential to prevent hypostatic pneumonia.

Patients hospitalized for chest or pulmonary injuries should be in private rooms. All attendants and visitors with respiratory infections should be excluded.[11]

5. *Treatment of Associated Conditions.*—Shock, hemorrhage and respiratory obstruction received first attention in pulmonary injuries. Patients with shock should be treated with oxygen by inhalation,[33] adequate doses of meperidine hydrochloride to alleviate pain and fear, and plasma or blood transfusions. Fluids should be given with caution in order to avoid acute pulmonary

[32] Dybdahl, G. L.: Control of Pleuritic Pain by Use of Cutaneous Anesthesia, Permanente Found. M. Bull. **2**: 30 (Jan.) 1944.

edema.[16] It is therefore better to use concentrated plasma or albumin preparations in cases without loss of blood.[34] Patients with pulmonary edema must not be given intravenous fluids, but should be treated with morphine, oxygen by inhalation under positive pressure[33] and intravenous theophylline ethylenediamine. Venesection may be a life-saving procedure in some cases of pulmonary edema.[34]

Hemorrhage in closed hemothorax is seldom alarming,[23] but if signs of bleeding or pulmonary tamponade become alarming, an open operation to ligate a torn vessel is imperative.[22] The current literature recommends the aspiration of hemothorax and partial replacement with air within thirty-six to forty-eight hours after injury.[35] Early aspiration was performed only twice in my series. Patients not treated in this manner had moderate fever which persisted for from five to seven days, or until the pleural cavity was aspirated.

Respiratory obstruction or massive collapse should be treated by aspiration of the mucous plug from the bronchial tree. Bronchoscopy may be a life-saving procedure. Tracheobronchial catheter suction is useful for the removal of accumulated tracheobronchial secretions.

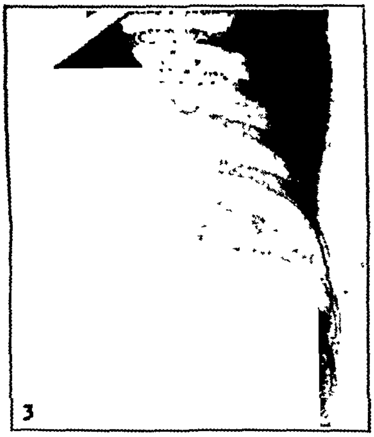

Fig. 3 (case 5).—Fracture of the eighth and ninth ribs on the left side in the midaxillary line.

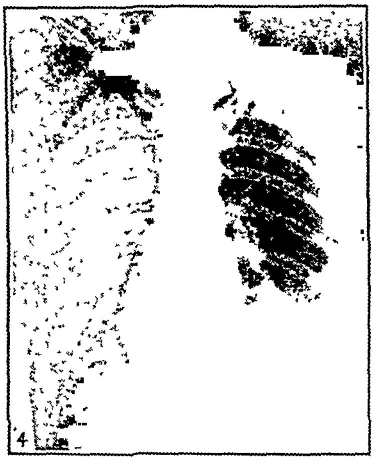

Fig. 4 (case 5).—"Contrecoup" pneumonia, lower lobe of the right lung.

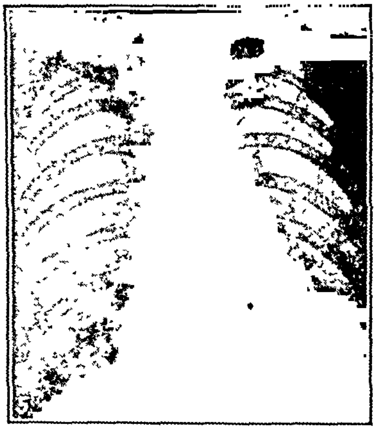

Fig. 5 (case 7).—Fracture of fourth to sixth ribs on the right side complicated by pneumothorax (right) and atelectasis (lower lobe, left).

Tension pneumothorax needs immediate aspiration and does not brook delay. Simple pneumothorax is treated conservatively. Subcutaneous emphysema does not require therapy unless the skin becomes dangerously tight or there is interference with the circulation. Multiple "pie-crusting" incisions are then indicated.

Stove-in chest with paradoxic respiration should be supported by adhesive strapping, sandbags, skeletal traction or skeletal fixation by wiring,[36] if necessary, in order to correct paradoxic respiration and increase the vital capacity.

6. *Treatment of Complications.*—Sterile pleural effusion does not need treatment unless it produces respiratory or circulatory embarrassment. The withdrawal of 1 liter of fluid by thoracentesis is safe. Larger amounts of fluids should be removed only with caution. Empyema may be treated with aspiration followed by intrathoracic instillation of 50,000 units of penicillin[37] once or twice a day. In this hospital, not a frank case of empyema was cured in this manner.[38] When the empyema fluid becomes thick, thoracotomy is indicated. Intrathoracic instillations of penicillin may be of value in aborting empyema in cases of sterile pleural exudates which contain abundant pus cells.

Pulmonary atelectasis can be relieved by the use of expectorants, inhalations of carbon dioxide and forced coughing on the part of the patient. Pulmonary edema complicating pneumonia can be successfully combated by the inhalation of oxygen under positive pressure and the intravenous injection of 0.5 Gm. of theophylline ethylenediamine, 50 cc. of 50 per cent sucrose solution and 250 to 500 cc. of plasma.[39] These may be injected every three hours as necessary.

Spread of the pneumonia to other lobes is an indication for intensive combined therapy with penicillin and sulfadiazine.

REPORT OF CASES

CASE 1.—*Typical Post-Traumatic Pneumonia With Intact and Unmarked Thorax.*—M. G., a white man aged 59, fell 8 feet onto the left side of his chest and left shoulder. The examination was negative except for the patient's subjective complaint of mild pain in the shoulder and chest. The only treatment advised was acetylsalicylic acid. Two days later the patient had a sudden onset of pleuritic pain in the left side, followed by a cough productive of bloody mucopurulent sputum. Physical and roentgenologic examinations revealed pneumonia in the lower lobe of the left lung. The sputum contained many type XXIX pneumococci. Treatment with sulfadiazine resulted in recovery in five days.

CASE 2.—*Development of Post-Traumatic Pneumonia in a Patient with Preexisting Pulmonary Disease Who Was Treated for a Chest Contusion by Adhesive Strapping.*—R. C., a white man aged 46, who had chronic asthmatic bronchitis of five years' duration, slipped and fell to the street and sustained a contusion of the left side of the chest. He complained immediately of pleuritic pain. The chest was strapped. Three days later he entered the hospital with type XI pneumococcic pneumonia in the lower lobe of the left lung. Recovery was uneventful after treatment with sulfadiazine.

CASE 3.—*Multiple-Lobe Pneumonia Following a Severe Blow Which Left the Thorax Unmarked.*—W. S., a white man aged 55, was struck across the anterior right side of the chest

by a pipe weighing more than 10 pounds. He was stunned and dyspneic for a short time only. Treatment was not given. Three days later a type IV pneumococcic pneumonia of the right lung developed (figs. 1 and 2). Recovery was uneventful after treatment with sulfadiazine.

Case 4.—*Pneumonia Following Injury by Eight Days in a Patient Treated With Codeine.*—H. P., a white man aged 35, fell off a ship into the San Francisco Bay. He was rescued immediately. His only complaint was pain in the left side of the chest. Codeine, 1 grain (0.06 Gm.) every four hours, was prescribed. The patient remained ambulatory but took the codeine continually until pneumonia developed in the lower lobe of the left lung on the eighth day. The sputum contained a moderate number of pneumococci which did not type. Recovery was uneventful after treatment with sulfadiazine.

Case 5.—*"Contrecoup" Pneumonia Which Followed Trauma by Seventeen Days. Previous Treatment by Complete Circular Adhesive Strapping.*—M. W., a white woman aged 31, fell in her home and sustained fractures of the left eighth and ninth ribs in the midaxillary line (fig. 3). The lower chest was completely encircled with adhesive strapping. Seventeen days later pneumonia developed in the right lower lobe (fig. 4). The sputum contained a moderate number of pneumococci which did not type. The patient stated that she had continual chest pain after the injury and that the chest strapping made it "impossible" for her to breathe.

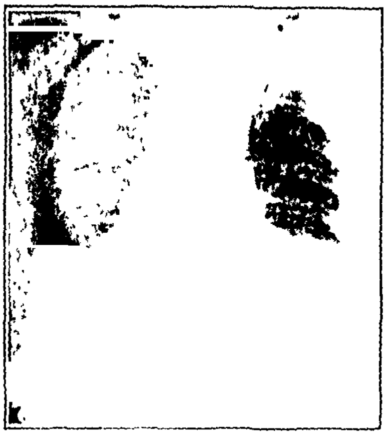

Fig. 6 (case 8).—Bilateral basal pneumococcic pneumonia.

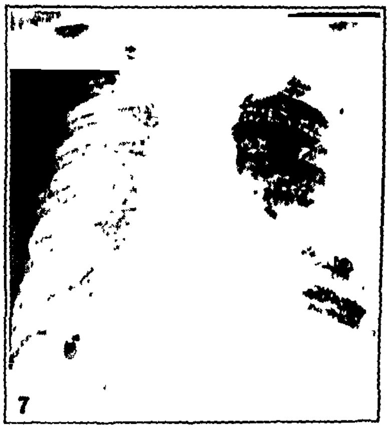

Fig. 7 (case 9).—Pneumococcic pneumonia, lower lobe of the right lung.

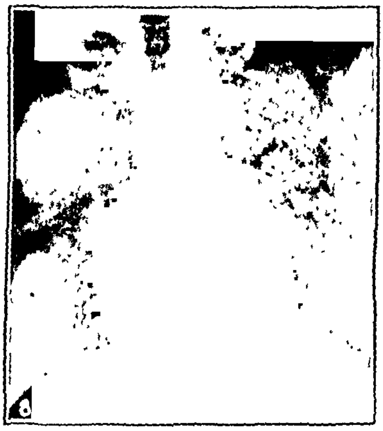

Fig. 8 (case 13).—Bilateral pneumonia on the eleventh hospital day after patient was struck by a crane.

Case 6.—*"Contrecoup" Pneumonia Following Trauma by Eight Days. Previous Treatment by Complete Circular Adhesive Strapping. Respiratory Infection at the Time of Injury.*—J. M., a white man aged 48, bumped the right side of his chest while working. He had continual pain in the right side for two days. His chest was then completely encircled from the nipple level down with adhesive tape. This relieved his symptoms, but six days later type XXXIII pneumococcic pneumonia developed in the lower lobe of the left lung. Recovery was uneventful.

Case 7.—*"Contrecoup" Pneumonia in a Patient with Pulmonary Contusion and Atelectasis.*—H. M., a white woman aged 34, was struck in the right upper side of her chest by a vehicle, sustaining fractures of the fourth to the sixth rib on the right side posteriorly near the spine. This was complicated by a pneumothorax on the right and an atelectasis of the lower lobe of the left lung (fig. 5). The chest was strapped, and no specific attempt was made to relieve the atelectasis. The next day signs and symptoms of pneumonia were present in the lower lobe on the left side. The sputum did not type out pneumococci. Recovery was uneventful after treatment with sulfadiazine.

Case 8.—*Another Case Which Demonstrated the Danger of Chest Strapping in the Presence of Pulmonary Injury.*—C. B., a white man aged 51, fell into a hole 5 feet deep, sustaining fractures of the seventh to the tenth rib on the left side in the axilla. The chest was strapped. The next day the patient complained of bloody sputum and increased pain in the chest. Examination revealed a friction rub and crepitant rales in the base of the left lung. Two days later the patient had findings of bilateral basal pneumococcic pneumonia (fig. 6).

Case 9.—*Pneumonia Following Injury by Thirteen Days in a Patient Treated With Adhesive Strapping.*—C. K., a white man aged 57, slipped and struck the ground with the right side of his chest, sustaining fractures of the fifth to the ninth rib on the right side in the posterior axillary line. The chest was strapped. The patient had continual pain and complained that he was unable to breathe deeply. Thirteen days after injury pneumococcic pneumonia in the lower lobe of the right lung developed (fig. 7). Recovery was uneventful.

Case 10.—*Pneumonia Following Fracture of Ribs Treated by Complete Encirclement of the Chest With Adhesive Tape in the Presence of Pulmonary Findings.*—W. D., a white man aged 56, fell 6 feet and struck the left side of his chest with a piece of lumber, sustaining fractures of the fifth to the tenth rib on the left side in the posterior axillary line. On examination of the chest, wheezes were found throughout the lung fields. A history of any previous respiratory symptoms was not obtained. Nevertheless, the lower chest was completely encircled with adhesive strapping. The next day the patient had pneumococcic pneumonia in the lower lobe of the left lung. Sulfadiazine therapy was instituted. Several days later the infection spread to the lower lobe of the right lung. The highest sulfadiazine blood level was 8 mg. per hundred cubic centimeters. A sterile pleural effusion developed, but the patient made a complete recovery after treatment with penicillin.

Case 11.—*Pneumonia Developing in the Presence of a Sulfadiazine Blood Level of Six Milligrams per Hundred Cubic Centimeters.*—G. N., a white man aged 56, fell 40 feet, sustaining a stove-in chest on the right side. Sulfadiazine was administered. Two days later pneumonia developed in the lower lobe of the right lung. The blood sulfadiazine level was 6.0 mg. per hundred cubic centimeters at the time. The sputum showed a few pneumococci which did not type. The pneumonia quickly spread to involve four lobes. Penicillin therapy was instituted, and the patient recovered in ten days, in spite of *pulmonary edema* on the fifth hospital day.

Case 12.—*Fatal Case of Pneumonia Complicated by a Ruptured Pancreas, Hemothorax and Laceration of the Parietal Pleura.*—L. L., a white man aged 45, was struck by a truck. The seventh, ninth and tenth ribs on the left side were fractured posteriorly. The patient was hospitalized and appeared to be in good condition except for abdominal distention. Three days later the patient became febrile, and it was apparent that he had bilateral pneumonia. The sputum was "loaded" with pneumococci which did not type. The leukocyte count was 36,750 per cubic millimeter with 91 per cent neutrophils. Urinalysis, which had been negative previously, showed 3 plus albumin and many casts. The patient died the next day, in spite of treatment with sulfadiazine. An autopsy revealed bilateral bronchopneumonia. The left pleural cavity contained 500 cc. of blood. The lungs were intact, but there was a laceration in the parietal pleura on the left. The pancreas was ruptured but intra-abdominal signs of acute hemorrhagic pancreatitis were not present.

CASE 13.—*Fatal Case of Post-Traumatic Pneumonia Complicated by Empyema.*—J. C., a white man aged 56, was struck across the anterior portion of the chest by a crane. He lost consciousness momentarily. Examination revealed evidence of injury to the head and chest. There was an area of ecchymosis under the left clavicle, and rales were present throughout the lung fields. Two days later a pleural friction rub was heard at the base of the right lung, and sulfadiazine was administered. The temperature remained around 100 F. A roentgenogram on the eleventh hospital day revealed a bilateral pneumonia (fig. 8). The sputum contained few pneumococci, but Mycobacterium tuberculosis was not found. A thoracentesis on the nineteenth hospital day revealed early empyema on the right which was treated with penicillin instillations for six days without avail. A resection of the ninth rib on the right side was done on the twenty-fifth hospital day. The empyema fluid removed at surgery grew Escherichia coli in pure culture. Five days postoperatively there was some hemorrhage from the wound, but this was controlled by packing. The next day the patient suddenly became restless and irrational and died. A coroner's autopsy was incomplete, and therefore the cause of death could not be established.

CASE 14.—*Fatal Case of Pneumonia Complicating Hemothorax.*—J. K., a white man aged 57, was struck by a train. He was not unconscious. His left humerus was fractured, and on the left side all the ribs from the fourth down were fractured. Subcutaneous emphysema was present bilaterally over the anterior portion of the chest. A roentgenogram showed a left hemothorax. This was aspirated later. On the second day pneumonia developed in the lower lobe of the left lung. One week later the pneumonia spread to the lower lobe of the right lung, and after an apparent recovery it relapsed. The patient died on the fifty-fourth hospital day. A coroner's autopsy revealed bilateral pneumonia and a healing laceration of the lower lobe of the left lung. The parietal pleura was intact.

SUMMARY AND CONCLUSIONS

In 73 cases of pneumonia following nonpenetrating injuries to the chest, 28 patients had an intact thorax and 45 had fractures of the thoracic cage.

Of the cases of primary pneumonia observed in this hospital, 2.4 per cent were post-traumatic. Over 92 per cent of the cases occurred within six days of the injury.

In 54 patients, pneumonia developed at the site of the direct trauma only.

In 19 patients pneumonia developed at the site of the "contrecoup" pulmonary injury; 9 of the 19 also had pneumonia at the site of the direct trauma.

The course and complications of post-traumatic pneumonia simulate those of mild to moderately severe primary pneumococcic pneumonia. The "higher type" pneumococci are the etiologic organisms usually found in post-traumatic pneumonia.

In consideration of the pathogenesis of pulmonary injury and post-traumatic pneumonia and the errors commonly made in the treatment of chest injuries which facilitate the development of pneumonia, it may be stated that the prophylaxis of post-traumatic pneumonia depends on: (1) the prevention of reflex pulmonary atelectasis, (2) the restoration of normal vital capacity, (3) the attenuation of thick, tenacious bronchial mucus, (4) protection of the patient from respiratory pathogens harbored by others, and (5) prophylactic chemotherapy with adequate doses of penicillin or sulfadiazine.

SIMPLIFIED METHOD FOR CALCULATING DIABETIC DIETS

ELIZABETH K. CASO, M.S.
and
FREDRICK J. STARE, M.D.
BOSTON

Numerous methods have been evolved for the calculation of diets to be used by patients with diabetes mellitus and for the simplified instruction of patients in the use of such diets. Some of these methods involve calculations which are unnecessarily accurate in view of the variable composition of foods, as affected by such factors as the variety of seed, the soil, climatic conditions and harvesting, storage and cooking methods. The fairly common practice of instructing patients to weigh diets can be criticized for the same reason plus the fact that a patient who is "tied to a pair of scales" has much less chance of living a normal life, which is so important from a psychologic point of view. The subject of the percentage of carbohydrate in foods, particularly vegetables, has also been confusing to the patient. In general, we have found that many patients disregarded it and ate whatever vegetable was prepared for them

TABLE 1.—*Food Equivalents*

List 1.—Protein Equivalents—Negligible Carbohydrate, 7 Gm. Protein, 5 Gm. Fat

Meat, fish, poultry—1 oz. (28 Gm.)
Egg—1
Cheese, American—1 oz. (28 Gm.)
Cheese, cottage—2 tbs.
Oysters, clams, shrimp—5
Sardines—3 medium
Salmon, tuna, crabmeat—¼ cup
Peanut butter—1½ tbs.
"Cold meat"—3 thin slices
Frankfurt—1 average size

List 2.—Vegetables—Negligible Carbohydrate, Protein and Fat

Celery
Cucumber
Lettuce
Radishes

List 3.—Vegetables—7 Gm. Carbohydrate, 2 Gm. Protein, Negligible Fat (1 Serving = ½ Cup)

Asparagus
Beans, string
Beets
Broccoli
Cabbage
Carrots
"Greens": beet, chard, dandelion, mustard, kale, spinach, turnip
Turnip
Onions
Squash
Tomato

List 4.—Fruits—10 *Gm. Carbohydrate, Negligible Protein* and Negligible Fat

Apple—½ medium
Applesauce, unsweetened—½ cup, scant
Banana—½ small
Berries: raspberries, blueberries or blackberries—½ cup
Cantaloupe—⅓ medium
Cherries—12 small
Dates—2 small
Grapefruit—½ medium
Grapefruit juice, unsweetened—½ cup
Grapes—15 medium
Orange—1 medium or ½ cup juice
Peach—1 medium
Pear—½ large
Pineapple, fresh, diced—½ cup
Pineapple juice, unsweetened—⅓ cup
Plums—2 medium
Prunes—2 medium
Strawberries—12 large
Tangerine—1 large
Watermelon—1 small slice with rind, ⅓ lb. (151 Gm.)

List 5.—Carbohydrate Equivalents—16 Gm. Carbohydrate, 3 *Gm. Protein, Negligible Fat*

Beans, baked and lima—¼ cup
Bread, baker's—1 slice
Corn—¼ cup (1 small ear)
Rice, macaroni, noodles—½ cup
Graham crackers—2
Soda crackers—5
Peas—½ cup, scant
Potato, white—1 small (size 5 to 1 lb., 454 Gm.)
Cereals, cooked—½ cup
Cereals, dry, flakes—1 cup

List 6.—*Fat Equivalents—Negligible Carbohydrate,* Negligible Protein, 4 Gm. Fat

Butter or fortified oleomargarine—1 tsp.
Cream, light—2 tbs.
Mayonnaise—1 tsp.
Oil—1 tsp.
Bacon—1 slice, long, crisp
Milk—(1 cup, 8 oz.) 12 Gm. carbohydrate, 8 Gm. protein, 10 Gm. fat

---

From the Department of Nutrition, Harvard School of Public Health, and the *Medical Clinic, Peter Bent Brigham Hospital.*

at home, irrespective of its carbohydrate content. This practice seldom accounts for more than a 5 to 10 per cent variation in the total carbohydrate intake for the day. Certainly most diabetic patients can tolerate that much variation in their carbohydrate intake.

Many methods of dietary instruction are impractical and unrealistic because they do not take into consideration the patient's food habits. Race, religion and economic status, together with other social and psychologic factors, fundamentally affect the daily selection of food. A laborer who takes his lunch from home presents one problem. His noon meal must be planned around the nonperishable, easily packaged foods. A person with a limited income may not be able to afford more than one serving of fruit and vegetables a day; therefore the carbohydrate in the diet should be figured from less expensive sources. An Italian patient is accustomed to using oil, "pastas," tomato sauces and salads and has definite food patterns. Thus we see that a diet adapted to individual food habits will have a much better chance of being eaten in its entirety.

Table 2.—*Summary of Composition of Food Equivalent Groups*

Foods and Equivalents	Carbohydrate	Protein	Fat
Milk—1 cup	12	8	10
Protein equivalents—list 1	0	7	5
Vegetables—list 2	0	0	0
Vegetables—list 3	7	2	0
Fruits—list 4	10	0	0

		68	62	50
Carbohydrate equivalents (list 5) whole grain or enriched	7 serv.	112	21	..
Fat or equivalents	3 serv.	..	..	12
		180	83	62

Another criticism of some of the diet plans in general use is that they may not contain adequate amounts of the essential nutrients, especially minerals and vitamins. For example, if the amount of milk allowed in the diet is appreciably limited, as it sometimes is because it is a source of carbohydrate, the diet becomes low in calcium and riboflavin. If breads and cereals are greatly restricted in amount, the diet may be low in thiamine. The consumption of gluten bread in the past has also been responsible for a lack of several elements of the B vitamin complex in the diet. The use of whole grain products or of bread and cereals made from enriched flour will tend to prevent this situation. With insulin therapy most diets may contain at least six servings of breads or cereals, which together with average amounts of the other basic foods will supply a normal intake of the vitamin B complex for the usual patient. The sample diabetic diet shown in table 3 illustrates the manner in which such a diet can be adequate nutritionally if it is planned around the basic food groups.

With these factors in mind, we have worked out a simple and useful method of dietary calculations that will result in a diet nutritionally adequate and practical for the patient. This short method has been devised primarily for the busy practitioner who does not have available the hospital or clinic facilities of a trained nutritionist; however, we have found it of equal value to the latter.

It is first necessary to have a simplified list of food equivalents; that is, common foods which furnish approximately the same amount of carbohydrate, protein and fat. This is given in table 1. More complete tables of food equivalents are to be found in any textbook of applied nutrition or dietetics. List 1 of this table gives the protein equivalents or foods which have approximately the same composition as 1 ounce (28 Gm.) of meat. We have taken as the average figure for these protein equivalents: carbohydrate—zero; protein—7 Gm.; fat—5 Gm. Vegetables vary in carbohydrate composition and have been classified by some authors as 3, 6 and 9 per cent or 5 and 10 per cent, according to the approximate amount of carbohydrate which they contain. To simplify this classification we have grouped together the raw vegetables which may be eaten in more or less unlimited quantity (list 2) since they contain negligible amounts of carbohydrate. The vegetables of the highest carbohydrate content, such as legumes, corn and potatoes, are included in the equivalents with bread and cereals in list 5. The rest of the vegetables are grouped together in list 3, and a serving of these vegetables, or one-half cup, is figured as 7 Gm. of carbohydrate and 2 Gm. of protein. These figures represent average values as determined by actual composition and weighted according to the frequency with which the foods are consumed. For example, over a period of one year patients were questioned in the Diabetic Clinic of the Outdoor Department, Peter Bent Brigham Hospital, regarding the types of vegetables they ate on the preceding day. Five hundred sixty-two reported eating a "5 per cent" vegetable and 482 a "10 per cent" vegetable. Thus, these observations help to substantiate the validity of using a value of 7 Gm. of carbohydrate per serving of these vegetables. Fresh fruits range considerably in their carbohydrate composition. Therefore, for uniformity the servings of fruits in list 4 are converted into amounts which yield approximately 10 Gm. of carbohydrate. List 5 consists of the carbohydrate equivalents. These foods have the same composition as one slice of (baker's) bread which has a value of 16 Gm. of carbohydrate and 3 Gm. of protein. Fat equivalents are given in list 6 and are equal to 1 teaspoon of butter containing 4 Gm. of fat. Since the composition of milk differs considerably from that of other foods, it is placed in a separate category. Moreover, it supplies many of the essential nutrients to the diet and, therefore, it is considered basic in the diet and should be included each day.

TABLE 5.—*Number of Servings of Carbohydrate or Fat Equivalents to Complete the Diet Prescription*

180 Gm carbohydrate in prescription
68 Gm. carbohydrate in diet from sources other than bread or equivalent
16 | 112 Gm.
7 servings of carbohydrate equivalents to fill prescription

60 Gm. fat in prescription
50 Gm fat from sources other than butter
4 | 10 Gm.
2½ or 3 tsp of fat equivalents to fill prescription

TABLE 6.—*Sample Day's Menu*

The carbohydrate is divided approximately in these meals on the basis of 2/7, 2/7, 2/7 and 1/7

Breakfast	Lunch	Dinner
Grapefruit—½	Toasted cheese sandwich	Roast leg of lamb—4 oz. (113 Gm)
Soft cooked egg—1	American cheese—1 oz (28 Gm)	Carrots—½ cup
Oatmeal—½ cup	Bread—2 slices	Mixed green salad
Whole wheat toast—1 slice	Fat—1 tsp	Small potato—1
Butter or oleomargarine—1 tsp.	Tomato salad	Bread, white, enriched—1 slice
Milk—1 cup	Prunes—2	Butter or oleo—1 tsp
Coffee	Tea	Orange slices
		Coffee

Night Lunch
Milk—1 cup and graham crackers—2

Table 2 summarizes the carbohydrate, protein and fat content of the various food equivalents listed in table 1. By the use of this table it is possible to calculate diet prescriptions with considerable ease and simplicity, taking into account the amounts of each of these food groups which the patient is desirous of eating. Nutritive adequacy of the diet is generally assured by seeing that at least one or more items from each of these food groups is included in the diet and by selecting a variety of vegetables and fruits in order to supply daily a serving of a green or yellow vegetable and of a fruit or vegetable which is a good source of ascorbic acid. Variety in the diet is achieved by making use of the food equivalents.

Tables 4 and 5 are specific examples of the use of this method in calculating a diet for a patient with diabetes.

To determine the number of servings of carbohydrate equivalents or fat equivalents required to complete the diet prescription, it is necessary only to:

1. Subtract the number of grams of carbohydrate (68) furnished by the other sources of carbohydrate in the diet from the amounts prescribed (180) and divide the result by 16, the number of grams of carbohydrate in one serving of carbohydrate equivalent.
2. Follow the same procedure with regard to fat, except to divide the result by 4, the number of grams of fat in one serving.

The amount of protein in any diet may be adjusted to the prescription by adding or subtracting 1 ounce (28 Gm.) of meat or its equivalent.

Table 6 gives a sample day's menu which is based on the foregoing diet outline and makes use of the food equivalents in table 1.

CONCLUSION

A simplified method for the rapid calculation of diabetic diets has been presented which should be of help to the busy practitioner.

INHERITANCE OF RETINOBLASTOMA

Two Families Supplying Evidence

HAROLD F. FALLS, M.D.
Ann Arbor, Mich.

It is my purpose in this paper to present two new pedigrees which lend support to evidence that retinoblastoma is a hereditary form of neoplasia. An increased interest in the genetic determination of such tumors has been evidenced in the medical literature of recent years. Weller[1] in 1941, Griffith and Sorsby[2] in 1944 and Rados[3] in 1946 carefully reviewed and analyzed the evidence that such malignant neoplasms of childhood may be the results of hereditary factors.

Weller cautiously concluded that there is no clearcut evidence to demonstrate that the predisposition to retinoblastoma behaves either as a simple dominant or as a simple recessive trait. This author postulates an inheritance of a somatic variation, possibly a structural anomaly, on which retinoblastoma may or may not develop. It was further suggested that retinoblastoma may belong to those congenital new growths which have been termed the "phakomatoses."

Griffith and Sorsby concluded that the tumor may be due to an irregular dominant gene; that is, to one which produces the neoplasm in a certain proportion but not in all of the heterozygotes who receive this gene. Waardenburg[4] states that in addition to domi-

nant inheritance a recessive gene may account for certain cases wherein consanguinity has been demonstrated in normal parents.

Observations on twins, and particularly on monozygotic twins, are of special value in human genetic research. These studies aid in assessing the role of heredity in the production of the trait being studied. Since identical twins are derived from a single fertilized ovum, they must have precisely the same genetic constitution or genotype. When monozygotic twins have similar tumors in identical organs at approximately the same age, much credence must be given to the role played by heredity in the determination of that tumor. It is of interest that the literature contains two carefully studied monozygotic twin pairs[5] in which both members exhibit retinoblastoma.

The two families which I shall describe have not previously been reported. They constitute Kindreds 502 and 574 in the files of the University of Michigan Heredity Clinic.

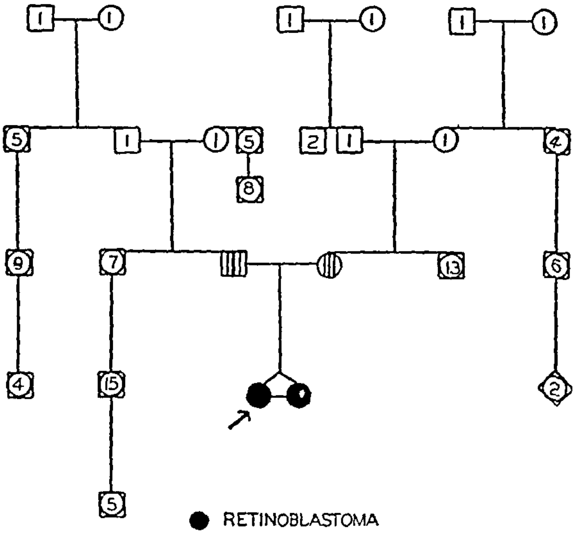

Fig. 1.—Kindred 502.

KINDRED 502

The pedigree chart reproduced in figure 1 follows the conventional plan of arranging siblings on a horizontal line in the order of their birth. All examined individuals were subjected to careful ophthalmologic study, and, in addition, data were secured on the color vision, A-B-O blood types, M-N blood types, secretor types and taste reaction to phenylthiourea.

The propositae for pedigree 502 are thought to be identical twins because they possessed a "single cord" and an identical blood type (OMN) and were remarkably similar in body proportions, facial features and pigmentation. Since the mother belonged to blood group OM and the father to group BMN, it will be seen that the twins could have been of different A-B and M-N types as well as of different sex had they been derived from two separate fertilizations.

The parents were of French and of Scotch-English descent. There was no known family history of ocular neoplasia, and evidence of consanguinity could not be obtained. Examination of the grandparents and aunts and uncles was refused because of certain prejudices.

CLINICAL PATHOLOGY

1. C. J. LaB., a girl aged 6 months, was first seen at the University Hospital Ophthalmic Clinic on July 26, 1943, at which time the parents had become alarmed about an apparent lack of vision which they had first noticed in the child at the age of 4 months. Physical examination showed that the length of body was 23¼ inches (59 cm.) and the weight 13 pounds (6 Kg.). The head was symmetrical. The anterior fontanel was patent and presented normal tension to palpation. The head circumference was 16 inches (41 cm.). The neck and thorax were normal and symmetrical. The heart rhythm and rate were normal. The lungs were clear. Neurologic abnormalities were not demonstrated.

The eyes showed eccentric wandering but would attempt light fixation. The external examination was normal bilaterally. Evidence of inflammatory change was not found. The lens and central media of the right eye were clear. The disk was oval vertically and of fair color and capillarity. Encroaching on the temporal disk margin and extending laterally across and beyond the macular area for at least 8 to 9 disk diameters was an extensive gelatinous pinkish gray mass *Many newly formed vessels were observed in the growth,* which extended into the vitreous for nearly 10 diopters. The remainder of the retina and its vasculature seemed normal. The intraocular tension was normal to palpation. Examination of the left eye revealed conditions similar to those of the right eye except that an additional smaller mass was seen just above and slightly nasal to the disk.

The diagnosis was bilateral retinoblastoma.

Roentgenologic examination of the orbits revealed minimal intraocular calcification in both eyes.

Enucleation of the right eye was advised for the purpose of pathologic study. The parents refused and wished to consider the alternative suggestion of roentgenotherapy before permitting hospitalization. During the course of the conversation it was revealed that C. J. had a twin sister, K. J., and the parents were strongly urged to bring her to the clinic for examination.

2. K. J. LaB. was first seen in the private office of Dr. F. B. Fralick at the age of 11 months. The parents reported that a bilateral gray reflex had been observed at the age of 6 months but that they had procrastinated in returning for examination. The child appeared to be in a good state of health and nutrition, and the physical examination revealed no clinical pathologic changes.

Ophthalmologic examination revealed eccentric roving of the eyes. The external findings were normal except for unduly dilated pupils which reacted poorly to direct light. There was no evidence of inflammation of the anterior segment of either eye. The intraocular tension was normal bilaterally to palpation. Funduscopy revealed that the entire posterior segment of each eye was occupied by a pinkish gray gelatinous appearing mass which was abundantly vascularized.

The diagnosis was bilateral retinoblastoma.

Bilateral enucleation or roentgenotherapy was advised

C. J. was also seen by Dr. Fralick at the same visit. It was reported that the child had shown symptoms of severe pain until spontaneous rupture had occurred at the age of 9 months. The globe collapsed, and soon the child grew more and more cachectic and constantly refused all feeding.

Ophthalmologic examination of the right eye disclosed that the anterior ocular segment was normal and that the posterior segment was filled with a tumor mass. Examination of the left eye revealed phthisis bulbi.

The parents refused therapy for C. J. and she died on March 5, 1944. Intracranial and posterior orbital extension was reported by a local physician.

Pathologic tissue obtained post mortem from the left eye was described by Dr. C. V. Weller as a collapsed eye showing productive inflammation and heavy calcification. The latter process was developing in the remains of a retinoblastoma, the greater part of which was necrotic. There was no evidence of penetration of the globe at the two sites examined.

K. J.'s course was much less spectacular than C. J.'s. The child gradually wasted away in cachexia until death ensued in June 1944. As in C. J.'s case, there was intracranial and posterior orbital extension of the tumor, and pathologic tissue study of the left eye revealed retinoblastoma with extensive necrosis and calcification.

KINDRED 574

Interest in the second family was stimulated by Dr. Gayle Mehney of Grand Rapids, Mich., who courteously referred the proposita to the Heredity Clinic. Dr. Mehney had diagnosed retinoblastoma in the left eye of this girl at the age of 3½ years. Enucleation was performed by Dr. Alfred Dean, Grand Rapids, and pathologic examination confirmed the clinical diagnosis of retinoblastoma.

When a pedigree of the family (fig. 2) was secured, it was revealed that ocular tumors were common in the sibship of the child's mother. More interesting still was the fact that the mother had her left eye enucleated at the age of 3½ years because of retinoblastoma. Five of the 9 siblings had had a diagnosis of retinoblastoma. Two of those affected survived to reach child bearing age.

III-1.—O. K. T., a boy, was born Dec. 17, 1887 and died Nov. 23, 1890. At the age of 4 months the child's nurse observed a "peculiar reflex from the left eye." Many local physicians were consulted, but no one recognized the nature of the ocular growth. Severe and increasing proptosis ensued. At the time of death large growths were noted in the neck. Abnormality of the right eye was not observed.

III-3.—H. W. T., a boy, was born on May 27, 1891 and died on July 21, 1891. It is reported that this child's left eye was involved in a manner similar to that of his brother, III-1. An enucleation was adivsed, but the parents procrastinated and death quickly followed. The globe was decidedly proptosed at death. The type and nature of extension were not recalled or recorded. It is thought that the right eye also was involved.

III-5.—A. R. T., a woman aged 52, born Sept. 1, 1894, reported an abnormal "light" was noted in the pupil of her left eye at the age of 2½ years. A diagnosis of retinoblastoma (glioma) was made by a local physician, and the eye was enucleated at 3½ years of age. The pathologic diagnosis was given as "glioma of the retina." This woman's only child, a daughter, aged 26, was found to be free of ocular tumors.

III-8.—J. M. T., a boy, who was born June 8, 1904 and died March 6, 1907, was known to have a defective left eye at the age of 1½ years. The eye was enucleated at 2 years of age, and "glioma of the retina" was the pathologic diagnosis. The vision in the right eye was reported as defective, but a description of the pathologic condition of the retina is not available. The presence of abdominal swelling at death suggests possible metastasis to the liver.

III-0.—A. M. T., a woman born Dec. 21, 1907, is the mother of the propositus. The tumor in her left eye was observed by a local physician when she was 3½ years of age and pathologic study of the enucleated eye revealed "glioma of the retina." Our physical and ocular examination in 1944 did not reveal any pathologic condition other than ocular prosthesis in the left orbit.

It is thought that II-1 died of a carcinoma of the stomach, and it is known that I-1 had a large pigmented nevus of the neck and arm. Death of the latter person was attributed to "apoplexy."

COMMENT

Pedigree 502 presents evidence of bilateral retinoblastoma in female identical twins occurring at approximately 6 months of age in both. In the absence of surgery or roentgenotherapy, a fairly rapid intracranial extension of the tumor led to the death of both children. This is the third reported instance wherein retinoblastoma has occurred in both identical twins.

Pedigree 574 contributes another family to the growing list of reported observations of the "vertical transmission" of the neoplasm.

One cannot be dogmatic in stating the mechanism of inheritance of retinoblastoma. In many of the reported pedigrees it appears that the tumor may be transmitted as an irregular dominant trait affecting only a portion of the gene carriers. Other families, however, could be interpreted as exhibiting a simple recessive mendelian pattern. That various types of inheritance may be encountered for a specific disease, in this instance retinoblastoma, is not unusual, for it is rather common to find that the same phenotype may have different genotypes. Macular degeneration of the retina, various forms of cataract, corneal dystrophy, glaucoma and retinitis pigmentosa are only a few of the human ocular anomalies which exhibit this phenomenon.

Since retinoblastoma is so frequently lethal at an early age, natural selection should be operating rather effectively against genes producing this tumor, provided the parents of such children do not make up this loss by increasing their fertility. If it is further assumed that the tumor is not rapidly on the decline, its incidence in the population is probably being sustained by a certain number of mutations or "new genes" in each generation. One should therefore expect a certain number of sporadic cases of retinoblastoma arising by mutation, and the case of twins described in this report may represent such an instance. A mutation, occurring either in oogenesis or in spermatogenesis, would account for both twins being affected.

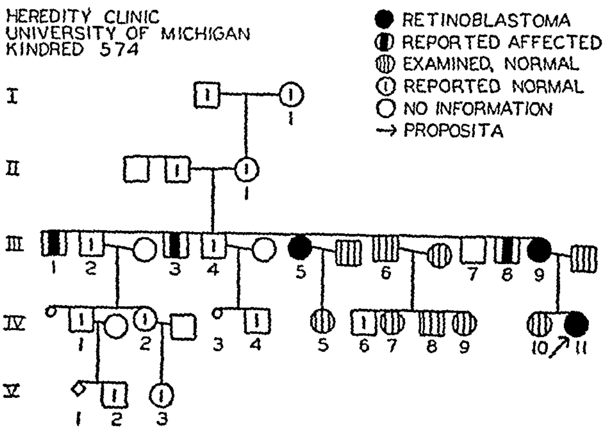

Fig. 2.—Kindred 574.

It is my sincere conviction that parents producing any child with retinoblastoma should be strongly urged to stop all child bearing. It is also advocated that any person surviving enucleation for retinoblastoma be sterilized.

The pathologic material encountered in both families was handled largely by outside sources, and in the case of pedigree 573 the material is no longer available. This is unfortunate, since it would have been of interest to compare the histologic appearance of the obviously inherited type of retinoblastoma with that of the occasional "sporadic" tumor. Cummings and Sorsby[6] could not discover any difference between the histologic character of a sporadic bilateral retinoblastoma and that of a proved genetic bilateral neoplasm.

SUMMARY

1. A family was observed in which retinoblastoma occurred bilaterally in identical female twins.

2. In a second family both the horizontal and the vertical occurrence of retinoblastoma was observed.

---

[6] Cummings, J. N., and Sorsby, A.: Unilateral and Bilateral Retinoblastoma, Brit. J. Ophth. 28: 533, 1944.

3. Retinoblastoma may have different genotypes, and it is not necessary to interpret all pedigrees in terms of a single mechanism of inheritance.

4. Parents who have produced a child with retinoblastoma should be urged to discontinue having children, and children surviving enucleation for retinoblastoma should be sterilized.

ABSTRACT OF DISCUSSION

DR. A. B. REESE, New York: I should like to cite two tragic instances illustrating the practical importance of what Dr. Falls has said. A father who in infancy had had both eyes enucleated because of retinoblastoma was not told of the danger of reproducing the disease, and his only child had bilateral retinoblastoma and bilateral enucleation. The child survives now after several years. A father who had bilateral retinoblastoma and bilateral enucleation in infancy was advised after marriage that it would be safe to have children. The first child had bilateral retinoblastoma and bilateral enucleation and now survives. Before the fate of the first child was known, a second child was conceived. This child also has bilateral retinoblastoma, for which an enucleation has been done on the more advanced eye. The fellow eye is being irradiated.

DR. C. WILBUR RUCKER, Rochester, Minn.: Dr. Falls, in presenting these two new pedigrees, has made a further important contribution to the literature on the inheritance of retinoblastoma. He points out that the tumor may be inherited in any one of a variety of ways in different families and that in some instances it seems to appear as a spontaneous mutation. Painstaking studies, such as this, should lead to a clearer conception of the various modes of inheritance of this disorder and should enable physicians of the future to give more helpful advice than we can give now. In the light of present knowledge certainly Dr. Falls is correct in urging that parents who have produced a child with retinoblastoma discontinue having children and that persons who survive enucleation for retinoblastoma remain childless. Toward the latter group, however, he is taking a hazardous step when he advocates sterilization during childhood. Society would benefit by it without a doubt, but the physician who performs a sterilizing operation on a child, in the absence of a specific statute to the contrary, makes himself liable to suit for assault, instituted by the patient when he reaches the age of 21 years. It would be my opinion that the physician should not risk the possibility of a ruinous legal suit, even for his convictions about eugenics, and that he had better content himself with giving advice on the use of contraceptives.

DR. HAROLD F. FALLS, Ann Arbor, Mich.: Retinoblastoma-like lesions have been produced by synthetic substances. In this respect it is important to state that the genes are complex chemicals and thus effect mutant changes, possibly in a manner similar to that of noxious agents. It is impossible for the clinician to differentiate, in many isolated cases, whether the anomaly in question is the effect of a genetic influence or that of a noxious chemical or physical factor. Dr. Rucker has suggested that it is legally dangerous to advise sterilization of minors. I agree, but, for the benefit of the race and also for the respective families to prevent the misery, the pain and the discomfort to both the parents and the affected individual, I would strongly emphasize the advocation of sterilization. We as physicians can only advise; the initiative falls on the parents.

Bacterial Endocarditis.—The success of the treatment of subacute bacterial endocarditis lies first in early diagnosis, which is hastened and confirmed by obtaining blood cultures three times daily for three successive days; second, in prolonged treatment with penicillin in adequate dosage; third, management of the cardiac failure; fourth, employment of general measures, especially blood transfusions and replacement of serum proteins; and, fifth, in the use of in vitro studies, which are of inestimable value in prognosis and in governing the course of therapy.—McMillan, Robert L.: Subacute Bacterial (Streptococcus Viridans) Endocarditis Treated with Penicillin, *Am. J. Med.*, December 1946.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association and Hygeia, the Health Magazine
Chicago

(*Continued from page 104*)

(NOTE.—*Following is the eleventh chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 11. *Growing Pains, 1875 to 1879*

1875

LOUISVILLE, KY.

The special committee on rank of the medical corps of the Army reported that it had used extraordinary efforts but had been unable to secure any action whatever from Congress. The Surgeon General of the Army expressed his thanks and his regret that nothing had been done; he was sanguine that in the long run the Army Medical Department would be successful if the American Medical Association would continue to take the same interest in the future as it had in the past.

Dr. J. Marion Sims was elected to the presidency of the Association.

Most important of the resolutions adopted was the determination that each year, until otherwise ordered, the President-Elect and permanent Secretary should direct an appeal in the name of the Association to the authorities of each state without a board of health, urging them to establish such boards. The Secretary was to report annually the names of states in which boards of health existed and also those which declined to establish them.

As a supplement to the annual Transactions the prize essay on "Excision of the Larger Joints of the Extremities" by H. Culbertson, M.D., was made available to the members.

1876

PHILADELPHIA

The celebration of the centennial of the United States was notably observed by the meeting in Philadelphia in 1876. The delegates were welcomed by Dr. William Pepper. He called attention to the tremendous progress that had been made by Philadelphia, which now boasted of 820,000 inhabitants and had the lowest rate of mortality of any city in the world with over half a million inhabitants. He felt that this was largely due to the lack of overcrowding in the city. Especially recommended to the delegates was a visit to the International Exposition then going on in Fairmount Park.

The President's address had dealt in part with syphilis; a motion was passed that 10,000 copies of that portion of his address be reprinted and distributed widely among the membership of the Association.

DR. SARAH HACKETT STEVENSON

At the meeting in Philadelphia in 1876, Dr. Sarah Hackett Stevenson was a delegate from the state of Illinois. She was the first woman member of the American Medical Association. When her name was called in the roll call, Dr. William Brodie of Michigan moved that the names of all female delegates be referred to the Judicial Council. This was on motion laid on the table. Dr. Stevenson, perhaps with remarkable wisdom, must have sat peculiarly quiet throughout the session since her name does not appear as a participant in the making of motions, the offering of resolutions the discussion of any papers or the presentation of any contribution.

Sarah Hackett Stevenson was born at Buffalo Grove, Ill., Feb. 2, 1849. She graduated from the Women's Medical College of Northwestern University and in 1874 went to Europe for two years' study where she worked with Huxley and Darwin. She began to practice in Chicago in 1876 and was sent as a delegate to the annual meeting of the American Medical Association in Philadelphia during that year. She was also the first woman to serve on the staff of the Cook County Hospital.

CONDEMNATION OF CULTISM

Another resolution suggested that members of the medical profession who in any way aid or abet graduation of medical students in irregular or exclusive systems of medicine are deemed thereby to violate the spirit of ethics of the American Medical Association.

STATE BOARDS OF HEALTH

The Secretary reported that boards of health "now exist in Alabama, California, Massachusetts, Michigan, Minnesota, Virginia and Wisconsin—but eight states in all." A careful counting will reveal only seven states listed as having state boards of health. He stated further that the matter was still being urged on the legislatures of the other states.

THE PHARMACOPEIA

Significant also was a resolution introduced by Dr. E. R. Squibb urging the American Medical Association to take the whole subject of the National Pharmacopeia into consideration for a review of its management. Dr. Squibb was requested to reduce to writing his plan for the Pharmacopeia. He found that already an interval of ten years embraced so much detail that it was becoming impracticable to handle it. It was his feeling that perhaps the American Medical Association should be the proper custodian of the Pharmacopeia and that perhaps the American Medical Association should take the leadership and invite cooperation of the American Pharmaceutical Association.

ADDRESS BY DR. J. MARION SIMS

In his presidential address Dr. J. Marion Sims recalled the meeting in Philadelphia in 1872 when so much time was wasted in discussing the woman physician question and the Negro question. He asserted that the Association was a truly representative body and that if any state or county medical society should send as a delegate either a woman or a Negro, the Association was bound to receive the delegate. He felt that the creation of the Judicial Council was a great step in advance in overcoming local problems of ethics which were a great source of annoyance and danger. Dr. Sims condemned particularly the system of education in which first, second and third year students sat side by side on benches at the same time and heard the same lectures year after year. He said:

> Already Chicago moves in the right direction; but Boston now takes the lead, and inaugurates the true scholastic method of classes, and terms of study, and courses of practical instruction, now fully appreciated by such young men as are in earnest in acquiring a thorough medical training.
>
> The Harvard method, with a salaried Faculty wholly independent of fees from students, is the only plan by which we can ever hope for a medical degree of any real value.

He urged the wealthy men of the country to increase the endowments of the medical schools. In his consideration of the Code of Ethics he doubted its significance, its validity or its constitutionality. It was susceptible of being used as an agent of persecution. "Let it stand as it is," he said. "Honorable men do not need its protection; dishonest men are not influenced by its edicts."

He urged widespread publicity concerning syphilis, which he considered the great problem of the day.

J. Marion Sims was opposed to licensure of prostitution as effective in the control of venereal disease. His answer was a system of sanitary inspection and control that would enable the health officer to take charge of those with syphilis and prevent them from spreading it through the community. Boards of health ought to have power to protect the public against all contagious and infectious diseases. He said he would simply include syphilis in the great family of contagious or communicable diseases and make it subject to the same laws and regulations used for their management.

1877

CHICAGO

Dramatic indeed was the opening of the meeting of the American Medical Association in Chicago on June 5, 1877. Dr. N. S. Davis welcomed the delegates; the Transactions said "Thirty-one years ago seventy-six gentlemen met in New York, representing the medical profession in the United States. Two thirds of the members have passed away, and he now failed to recognize a single face, in the meeting today, that was present on that occasion." At that moment a hand was raised, and Dr. N. S. Davis recognized Dr. Washington L. Atlee of Philadelphia, the only physician present who was one of the original seventy-six. Only twenty-nine years had passed since the organizational meeting in New York City, and yet that twenty-nine years had seen the departure from life of many of the great leaders of the previous generation.

ADDRESS OF DR. HENRY I. BOWDITCH

The President of the Association, Dr. Henry I. Bowditch of Boston, pointed out that the American Medical Association had united the physicians of the country, ironed out local idiosyncrasies and brought together men from every section. He remembered that wine flowed freely at public and private gatherings of an earlier day and that there had been occasional disorder observable during the debates but that the Association from this disorder had cemented friendships, so that it became one of the bulwarks of the state and a help toward civilization on this continent. By 1876 he felt, however, that the American Medical Association had lost repute in the Eastern and Middle states and with some of the leaders of the Western and Southern states. This, he felt, was due to two general causes: (1) the furious discussions on points of order and the ethics of professional etiquette and (2) the consciousness that the Association had been expected to produce results in the advancement of medicine and of professional stature out of all reason. He felt also that some of the meetings of the scientific sections had been used for the presentation of "papers or remarks from individuals, smitten with the *cacoethes scribendi aut loquendi*" and that they had not always had the ability or the will to check them. He also felt that the Transactions of the Association were too bulky and included now some papers that had been printed elsewhere and really constituted nothing in the way of advancement.

Another cause of disturbance was the passage of resolutions with lack of sufficient information, but which, nevertheless, compromised the entire Association. Finally, it was claimed, the Association was too democratic. Having ventured these criticisms, Dr. Bowditch offered suggestions for the improvement of the sections and for procuring scientific contributions. He praised highly the work of the Judicial Council in its settlement of questions of dispute. He urged that the social meetings include women and abandon alcoholic drinks.

He urged also, for the first time, that every member of a state medical society become a permanent member of the American Medical Association. Finally, he suggested a smaller delegation in the House of Delegates as representative of the membership.

The remainder of his address dealt with the possibility of association with the Canadian Medical Association and with the Pharmacopeia. He urged support for the Army Medical Library and Museum and of the American Medical College Association.

This address having been referred to a special committee, a report was received leading to improvement of the sections. The committee did not favor any change in the present plan of organization and considered association with the Canadian Medical Association impracticable.

The meeting in Chicago in 1877 was most impressive to Dr. Charles B. Johnson, who attended as a delegate from the Illinois State Medical Society at Champaign, Ill. The meeting was in the Palmer House and there were no elevators, so that guests climbed to the top stories. Dr. Johnson recalled seeing the venerable Dr. S. D. Gross of Philadelphia mounting the stairs laboriously. Dr. Gross stopped for a brief chat with Dr. J. Marion Sims, who had been President the year previously, and Dr. Johnson heard the renowned gynecologist say that "if he had his professional life to live over he would by hook or crook try to get more money out of it."

The address of Dr. Bowditch he remembered for a long time because of the recommendation that the American Medical Association conventions be conducted on temperance principles.

When Dr. Bowditch attended the meeting of the American Medical Association in Chicago in 1908, one of the sessions was held in a German hotel and the refreshments consisted of beer and pretzels. He tried to get a cup of coffee, but the waiter told him it could not be had. Then he asked for a glass of water. The waiter looked at him in astonishment but finally served the water.

PHARMACOPEIA VS. DISPENSATORY

At this point Dr. E. R. Squibb of New York presented a report on the revision of the Pharmacopeia. The underlying grievance was a personal matter between Dr. Squibb and Dr. H. C. Wood of the U. S. Dispensatory. Dr. Squibb began to read at 10 o'clock and was still reading at 11 o'clock. After another considerable period, a motion was made that Dr. Squibb be permitted to resume on Thursday at 12 noon and be given twenty minutes in which to finish his remarks. The remainder of the session was to be given to those entertaining opposite views to those of Dr. Squibb.

Intervening was a prolonged discussion on representation of homeopathic groups and the licensure of homeopathic physicians in various states.

When Dr. Squibb again began reading his address it was discovered that he could not conclude, and he was given additional time. He continued reading until the expiration of this additional time, and then, since he had not concluded, the Association proceeded to elect its officers.

Following the election by vote, a committee of five was appointed to examine the papers of Dr. Squibb and of Dr. Wood and of others and to determine the extent to which the American Medical Association should participate in the Pharmacopeia.

THE STATE BOARDS OF HEALTH

On the final day of the session, attention was called to the fact that the American Medical Association through its President and Secretary had urged the governor in every state to establish a state board of health. A resolution was passed urging the President and the Secretary of the Association to continue such an appeal year after year to the governor in every state until such state boards of health should be established. This was one of the most fundamental contributions made by the American Medical Association to the advancement of public health in the United States.

NEW SECTIONS

Now came appeals for the establishment of a new section on ophthalmology, otology and laryngology, since these specialties had assumed full stature with surgery and internal medicine.

INCREASED MILITARY MEDICAL RECOGNITION

A report was made from the committee that had urged on the Congress the establishment of better recognition of the medical staff of the U. S. Army. By this time the efforts of the committee had achieved some success. A letter from Surgeon General Joseph K. Barnes of the U. S. Army thanked the committee and expressed appreciation of the influence exerted in behalf of the medical officers of the Army by the American Medical Association.

1878

BUFFALO

Extensive reports were made by the delegates who had visited the Canadian Medical Association, the British Medical Association and the International Medical Congress of Geneva. The report from Geneva urged the possibility of developing a uniform pharmacopeia throughout the world—an ideal still sought in 1946 by the Health Organization of the United Nations.

HOMEOPATHIC PROBLEMS

The Judicial Council presented to this meeting charges against the Michigan State Medical Society for having elected as a delegate to the American Medical

Association one Dr. E. L. Dunster of the University of Michigan "knowing him to be engaged in aiding and abetting the graduation of students devoted to an exclusive dogma in medicine." Nothing had been found in the Principles of Ethics which would bear directly on the charges. From time to time resolutions had been adopted referring to the practice of cultism, but these resolutions did not constitute a part of the Code of Ethics. This report was discussed freely. Finally, a motion was made asking the Judicial Council to report at a subsequent meeting a law to meet the case in question.

At the meeting of the next day, Dr. Nathan Smith Davis proposed the following addition to the Principles of Ethics:

> And hence it is considered derogatory to the interests of the public and the honor of the profession, for any physician or teacher to aid, in any way, the medical teaching or graduation of persons knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine.

ORGANIZATIONAL PROGRESS

The Buffalo meeting elected Dr. Theophilus Parvin, then of Indiana, President.

An extensive report by a committee of N. S. Davis and S. D. Gross concerned the recommendations made by the President, Henry Bowditch, in the year previously. These two leaders were not inclined to accept the suggestions of Dr. Bowditch as to changing the nature of membership in the House of Delegates. They had some alternative proposals as to the selection of papers for the sections and as to the decisions on publication of papers. Dr. Bowditch submitted for himself a minority report disagreeing with them, but the majority report was adopted.

Ultimately the ideas of Dr. Bowditch as to representation in the House of Delegates and the consideration of papers read in the sections prevailed. The improvement in general quality of the medical profession, the raising of medical standards, the organization of the state medical societies and the advancement of medical science made the suggestions wholly logical.

The committee which had been urging the establishment of state boards of health was happy to announce that three additional states had founded boards of health so that now there were nineteen in all.

RESTRAINT OF THE INSANE

Psychiatry was discussed, and a resolution was adopted that the personal restraint of the insane is an essential element in the treatment of their disease. Nevertheless it was recognized that the state had a right to surveillance or legal regulation over restraints on the insane in order to punish any abuses of the right of restraint.

The report on the Michigan State Medical Society and Dr. Dunster indicated that there was no law by which the Michigan State Medical Society could be found in conflict with medical ethics. Immediately thereafter an amendment to the Principles of Ethics was adopted as previously suggested, and this took care of the situation.

PROMOTION OF THE PUBLIC HEALTH

In his presidential address Dr. T. G. Richardson paid attention to the improvement in the sections. The most significant portion of his address dealt with the creation of the state boards of health and the prevention of illness as their proper field of activity. He urged particularly better education of the public in regard to health and spoke with scorn of the gentleman who took his 14 year old daughter out of a first class school because a human skeleton was brought into the classroom by the professor of physiology, who was going to teach the pupils a few facts in regard to respiration and circulation. Dr. Richardson opposed federal control of public hygiene, but he recognized the necessity for a federal agency to prevent the introduction of contagious and infectious diseases from abroad. The 45th Congress had taken the first action since 1799 toward enforcing public health laws. Here is the concluding paragraph from Dr. Richardson's address:

> Whatever doubts there may be as to the extent of the authority possessed by the central government, there seems to be no dispute that within the limits of each separate state resides a power which with reference to all such matters is practically supreme. It is to this power represented by the legislature and executive of each state that we must look for the enactment and enforcement of such laws as state medicine demands of a wise government, economical not less of the lives and health of its citizens than of its material resources. It is therefore upon this power that the state medical societies should concentrate all their influence, professional and social, to effect the necessary legislation. They should employ their best endeavors to have state boards of health created where these do not exist, and they should by all means secure the right of nomination for appointment upon such boards; otherwise positions which demand men of peculiar qualifications and sterling integrity will be conferred, as is too often the case, upon mere office hunters, who have no interest whatever in the matter beyond its pecuniary return.

1879

ATLANTA, GA.

Organizations fall into strange traditions of action; patterns are followed until suddenly comes realization of hazard on the path. Dr. Joseph P. Logan of Georgia, who welcomed the delegates to Atlanta on May 6, 1879, stated frankly that he had looked up the previous copies of the Transactions of the American Medical Association to discover how an address of welcome ought to be made. He decided to do a job for Atlanta which "has sprung, in little more than a decade, into a city of 40,000 people." Remember that Atlanta had been devastated by the war. "We have not, however, my friends, sat down in ignoble lamentations over our misfortunes, but have gone to work with energy and determination to rebuild and make better our desolated places." These words are the beginning of a sentence which then continues without interruption for sixteen printed lines having to do with the industries, the works and the climate of Atlanta.

THE METRIC SYSTEM

The report on the International Medical Congress pointed out that the United States Marine Hospital services had adopted the metric system, which was found to work very well, and that it had been adopted by all nations except two—the United States and England. Later in the session a resolution was adopted that the metric system be official and be used in the Transactions. The agitation regarding the metric system was to go on and on for many years; the end is not yet.

A message of congratulation was sent from the convention to Ohio which had passed a bill making possible the dissection of human bodies.

The Association was still disturbing itself as to how to get some prize essays written that would be worthy the name; now four prizes of $250 each were established for strictly original contributions to medical and surgical progress.

ETHICAL RELATIONS AND CULTISM

Especially significant was the debate on the amendment to the Principles of Ethics having to do with exclusive systems of medicine. Because the attendance in Atlanta was small, the resolution was permitted to lie over until the following year.

The representative body also heard of action taken by the section on state medicine and public hygiene in response to an address by Dr. John Shaw Billings on securing statistical data on disease and mortality.

NOTE ON PROPRIETARY MEDICINES

A resolution was offered and referred to the Judicial Council protesting the placing on the market of drugs and combinations of drugs with copyrighted names. This seems to be the first mention of the practice which bore bitter fruit for the American people for many years.

The presidential address of Dr. Theophilus Parvin declared that medicine was the queen of the sciences. He then discussed the philosophy of science and of medicine with sixty references to bibliographic material. It seems to constitute the most learned document presented up to that time as a presidential address; but it concerned itself not at all with any immediate affairs. One reads it again and again puzzling over its meaning and significance, and at last one thinks of that stanza of Omar Khayyam:

Myself when young did eagerly frequent
Doctor and Saint, and heard great argument
About it and about: but evermore
Came out by the same door wherein I went.

Clinical Notes, Suggestions and New Instruments

AVOIDANCE OF ALLERGY TO LIVER EXTRACT

C. J. SULLIVAN, M.D., and G. O. BROUN, M.D.
St. Louis

One of the difficulties encountered in the treatment of macrocytic anemias with liver extract has been the development in occasional patients of allergic reactions to the liver extracts employed. Schwartz and Legere[1] in a recent article suggested that such allergic reactions may be avoided by changing the "brand" or type of liver extract, by reducing the dose of liver extract, by desensitizing with liver extract or by utilizing a histamine-protein complex as an antigen to produce histamine antibodies. The successful use of folic acid in the treatment of macrocytic anemias[2] suggests the possible value of this material in avoiding the effects of allergy to liver extract.

We have recently observed a patient suffering from addisonian pernicious anemia whose course was complicated by the presence of allergy to liver extract administered by parenteral injection. The sensitivity appeared to be organ-specific rather than species-specific since both hog liver and beef liver produced anaphylactic-like reactions. A minute dose of hog liver produced an immediate mild allergic reaction. A change to beef liver was effective in the avoidance of an allergic reaction as long as the dose was kept small. A large dose produced a severe allergic reaction. Folic acid therapy was instituted with dramatic and satisfactory response. In order to obtain maximum erythrocyte and hemoglobin levels, dosages of dried stomach extract and iron and sodium citrate were added to that of folic acid. The patient has been rendered free of symptoms and maintained at an erythrocyte level of more than 4,000,000 per cubic millimeter, with more than 13 Gm. of hemoglobin per hundred cubic centimeters of blood. The period of observation extended over eighty days of folic acid therapy.

REPORT OF CASE

History.—Mrs. C. C. was admitted to the University Hospital on March 30, 1946 complaining of weakness and pain in the legs. For the past four years she had been receiving from her physician injections of liver extract at regular intervals for treatment of anemia. In November 1945 within fifteen minutes after she had been given an injection of liver extract, itching of the palms, edema of the face and tongue and dyspnea developed, and the patient soon became unconscious. Epinephrine was administered and she recovered, gradually returning to normal during the subsequent forty-eight hours. Parenteral injections of liver extract were then discontinued, and liver extract and ferrous iron were given by mouth. During the next four months her anemia became progressively worse, and she noted profound weakness.

For many years she had had varicosities of both legs. In September 1943 a localized, tender mass had developed in the left femoral region, which had been treated by rest in bed and by the application of ice bags to the affected part. During the month preceding this hospital admission she had been experiencing, at irregular intervals, sensations of substernal constriction of gradual onset, associated with faintness and profound weakness. There was, in addition, a sensation described as "bubbles" moving upward along the course of the veins of the legs, most noticeable at night in bed. Ten years ago she had undergone a hemorrhoidectomy. She had migraine for several years during early adult life and chronic constipation. Her past history was otherwise not relevant.

Physical Examination.—The patient appeared well nourished. The skin was a light lemon color; the hair was white. The general appearance was that of weakness and apathy. The tongue was pale and smooth, and the papillae were atrophic. The lips and oral mucosa were pale. There was sclerosis of moderate degree of the peripheral arteries. The blood pressure was 120 systolic and 60 diastolic. There was a soft systolic murmur at the cardiac apex. Dilated, tortuous, superficial veins were seen over the posterior, lateral and medial surfaces of both lower extremities, with one area of tenderness and increased heat over the medial aspect of the lower part of the left leg. The deep veins were found to be patent. Roentgenologic examination revealed that the heart was 17 per cent larger than the average normal with uniform widening of the aorta. Gastric achlorhydria was found. A proctoscopic examination did not reveal any abnormalities. Roentgenologic examination of the gastrointestinal tract showed slight herniation of the stomach through the esophageal orifice, a diverticulum of the jejunum and ptosis of the colon. Serial electrocardiograms showed only axis deviation to the left. Roentgenograms of the legs showed a slight degree of arteriosclerosis.

Hospital Course.—Since at the time of admission it was believed that the patient might be experiencing small pulmonary emboli, it was deemed advisable, in view of the physical observations and the past history of thrombophlebitis, to consider ligation of the veins of the legs. Dr. John W. Stewart saw the patient as a surgical consultant and recommended bilateral saphenous ligation. Accordingly, on April 1, 1946, two days after admission, the long saphenous veins on both sides were ligated at their junction with the femoral veins. The patient experienced postoperative shock, controlled by the administration of 1,000 cc. of whole blood. The accompanying chart

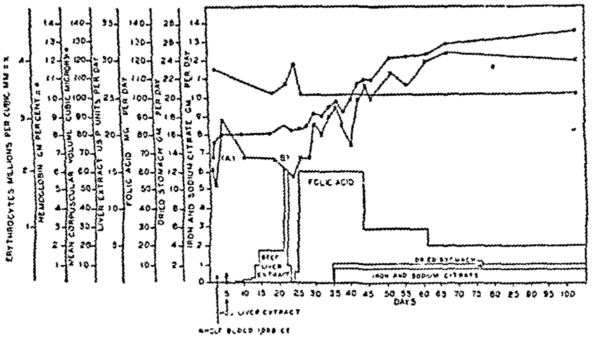
presents the antianemic medicaments used and the concomitant data on examination of the peripheral blood. It will be noted that liver extracts were at first administered in extremely small dosage, prepared by dilution of the original extracts.

COMMENT

This patient's type of anemia was macrocytic. The mean corpuscular volume determinations fell within a range between 118 and 102 cubic microns. The mean corpuscular hemoglobin concentration fell within a range between 32 per cent and 38 per cent. The presence of achlorhydria together with the absence of gross organic disease of the gastrointestinal tract or liver, and the history of an adequate dietary intake, justify by exclusion of other factors the diagnosis of addisonian pernicious anemia. It is of interest that the mean corpuscular volume and the mean corpuscular hemoglobin concentration have both remained at high levels at the termination of this period of observation, in spite of the absence of anemia.

Whole blood in the amount of 1,000 cc. was administered to combat postoperative shock. It will be seen from an inspection of the accompanying chart that this was followed by a sharp rise in the erythrocyte level, followed by a gradual decline. Three weeks later the erythrocyte count had declined to the pretransfusion level.

An extract of hog liver was administered in a single small dose (0.15 U. S. P. units). This was sufficient, however, to produce itching of the palms. It was probably a type of hog liver extract whose administration to the patient over a period of four years had eventually resulted in sensitization and shock, since most commercial liver extracts are hog liver preparations.



Response to various forms of treatment; *A*, allergic reaction, mild: itching of palms. *B*, allergic reaction, severe: itching of palms, vomiting, weakness and cold extremities, with persistence of symptoms for twenty-four hours.

Beef liver extract was administered over a period of fourteen days. This extract was well tolerated by the patient as long as the dosage was small; in fact, a dose of 2 U. S. P. units given twice a day did not produce allergic reaction, whereas 0.15 U. S. P. unit of hog liver had done so. However, when 15 U. S. P. units of beef liver was administered a violent shock-like reaction occurred. It is of interest that the erythrocyte count fell progressively during the fourteen days of beef liver therapy. A transfusion of 1,000 cc. of whole blood had been given one week before the administration of beef liver was started. A distinct rise in the red blood cell count and hemoglobin level was noted five days after folic acid therapy was begun and before dried stomach was added to the therapeutic regimen. The erythrocyte count had increased by more than 1,000,000 cells.

The exact role played by the dried stomach can not be properly evaluated. This preparation was administered, together with iron and sodium citrate, after the initial rise in the red blood cell count and hemoglobin level produced by the folic acid, when the erythrocyte count was greater than 3,000,000. In this case, unlike some of the other cases reported in which folic acid alone was administered, the response was maximal and sustained. The end result of this combination of folic acid, stomach extract and iron and sodium citrate was an entirely satisfactory increase in the number of erythrocytes to above 4,000,000 and in the production of hemoglobin to more than 13 Gm. per hundred cubic centimeters. It is noteworthy that the macrocytosis has persisted. The patient is now living a normal life and is free of those symptoms which were responsible for bringing her under observation. It is unlikely that liver extract, if tolerated, would have produced a more perfect result. It is probable that the disease would have terminated fatally had not treatment with folic acid and dried stomach been used.

SUMMARY

1. A case of macrocytic anemia with organ-specific allergy to liver extract is reported.

2. Administration of folic acid followed later by that of dried stomach and iron solved the serious problem of persistent allergy to liver extract and resulted in maximal and prolonged maturation of erythrocytes.

ADDITIONAL NOTE: The blood values after seven months of continuous medication with the same dosage were as follows: red blood cells, 4.25 million; hemoglobin, 12.75 Gm. per hundred cubic centimeters, and mean corpuscular volume, 90 cubic microns.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1946, p. 395).

The following dosage forms have been accepted:

H. E. DUBIN LABORATORIES, INC., NEW YORK

Aminophylline (Powder): 15 Gm., 113 Gm., and 454 Gm. bottles.

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Aminophylline (Powder): 28.35 Gm. and 113.39 Gm. bottles.

Tablets Aminophylline: 0.1 Gm. and 0.2 Gm.

Enerals Aminophylline: 0.2 Gm. Each tablet is enteric coated with a shellac-castor oil mixture.

Solution Aminophylline: Ampuls 0.25 Gm. in 10 cc. and 0.5 Gm. in 2 cc.

ZEPHIRAN CHLORIDE (See New and Nonofficial Remedies, 1946, p. 113).

The following additional dosage form has been accepted:

WINTHROP CHEMICAL CO., INC., NEW YORK

Zephiran Chloride Solution (Concentrate) 12.8%: 118 cc. and 3.79 liter bottles. A concentrated solution of Zephiran Chloride which may be diluted with water or isotonic salt solution before use.

Zephiran Tint: 1.81 Gm. vials, D and C red No. 39, for use in the preparation of colored Zephiran Chloride Solutions.

METHENAMINE (See New and Nonofficial Remedies, 1946, p. 176).

The following dosage form has been accepted:

E. S. MILLER LABORATORIES, INC., LOS ANGELES

Tablets Methenamine: 0.3 Gm.

SULFADIAZINE (See New and Nonofficial Remedies, 1946, p. 181).

The following dosage form has been accepted:

E. S. MILLER LABORATORIES, INC., LOS ANGELES

Tablets Sulfadiazine: 0.5 Gm.

MANNITOL HEXANITRATE (See New and Nonofficial Remedies, 1946, p. 336).

The following dosage form has been accepted:

THE SMITH-DORSEY COMPANY, LINCOLN, NEB.

Tablets Mannitol Hexanitrate: 30 mg.

SATURDAY, JANUARY 18, 1947

PLANNING FOR HEALTH

On January 3 Hon. Robert A. Taft, senator from Ohio, spoke over the facilities of the National Broadcasting Company on "A Republican Program." In the course of the address, which appeared later as "Extension of Remarks" in the *Congressional Record*, Senator Taft referred briefly to the place of health in the program. He said:

> So also in the health field we are proposing a program to assist the states and local governments in making their treatment of the indigent and medically indigent more systematic and complete We should encourage the formation of plans for voluntary health insurance to be available to those who wish to take it out. On the other hand, we strenuously oppose the Wagner-Murray-Dingell bill, which attempts to impose a complete system of compulsory sickness insurance on all the people in the United States. That plan would tax the people to raise four or five billion dollars a year to pour into Washington to be used by a federal bureau to pay all the doctors to give free medical care to all the people of the United States. It is not only a socialization of medicine but it is the federalization of medicine. No other measure before the American people proposes such a tremendous increase in the right of the federal government to interfere with the daily lives of the people. It flies in the face of every principle for which the Republican Party stands.

The language is direct; the principles are sound; the message is heartening!

In his message to the Congress on the state of the nation, President Truman indicated in vague generalities his belief in the desirability of better availability for medical care. Then on January 10 he sent to the Congress his budget and his message, in which he was somewhat more explicit. He said:

> Recent legislation for hospital construction, for increased activities in mental health and for expanded maternal and child health services are substantial achievements toward improving the substandard health level of a large part of the population. But the major problem of financing health care still persists. Therefore I again urge the Congress to enact a health insurance program which will make adequate medical care available to every one and provide protection against the economic hardships of sickness. Such a program should be almost entirely self financing through payroll contributions.

Last year the President carefully explained several times that he did not believe this program to be "socialized medicine." That excursion into semantics was of little avail in convincing the American people. Now taxes are referred to pleasantly as "payroll contributions." Moreover, the medical care of all the people by a bureaucracy is characterized as "health insurance." Isn't it really "federalized medicine"?

On January 10 also Senator J. William Fulbright, Democrat of Arkansas, for himself and Senator Robert A. Taft, Republican of Ohio, introduced a proposal for a new Department of Health, Education and Security in the Cabinet. This proposal would put all health, social security and educational functions of the government under supervision of a new Cabinet officer. Already conferences are being developed in which representatives of various national organizations concerned with these functions in our civilization will meet to interchange views on the principles which should prevail in the establishment of such an agency and on the qualifications of the personnel selected to administer the services. The proposal would seem to be a much needed step toward assembling the medical functions of the federal government in a single agency with direct access to the Cabinet. This is a principle for which the American Medical Association has contended since its organization one hundred years ago. The fact that President Truman suggested its adoption in his message this year and that the proposal comes under joint sponsorship of both major political parties would seem to indicate likelihood of early enactment.

In his message President Truman referred also to the desirability of legislation in behalf of the establishment of a National Science Foundation. At a recent meeting of the American Association for the Advancement of Science, leaders in many fields of science, including medicine, proposed early conferences with a view to improving on the text of the Kilgore-Magnuson bill, which passed the Senate last year. On this subject Senator Taft said recently:

> We are also proposing a measure to set up a permanent scientific foundation to promote research in many fields. Our measure creates a scientific council of fifty leading scientists to select the director and determine the scope of the work. This is a substantial modification of the Kilgore-Magnuson bill of the last session, which authorized the President to appoint a director with fifteen bureau chiefs and an elaborate organization, directly subject to political pressure.

Here again there would appear to be a desire to give government back to the people!

In concluding his message Senator Taft said:

> In every field they will invite counsel from the best minds, initiate studies and recommend measures for future enactment.

Physicians who have fought unceasingly in behalf of the fundamental principles of freedom in the intimate affairs of our lives and in the further advancement of medical science, which has reached, under our system of government, the highest level ever attained anywhere in the world, will read in these words a promise of success for our objectives. Physicians know the importance of unimpeded respiration for health and vitality. Apparently we may—at least for a time—breathe easier.

VAGOTOMY FOR PEPTIC ULCER

Animal experiments in which a Pavlov or Heidenhain pouch was utilized have demonstrated that pure gastric juice has an aggressive action on living tissue as contrasted with that of the usual gastric content. The composition of the material in the stomach is usually a mixture of swallowed food and saliva, gastric juices from the parietal cells of the fundus, a mucous and a neutral or faintly alkaline secretion from the pyloric antrum and varying quantities of regurgitated duodenal juices. This material is relatively inert. Carlson demonstrated that a continuous gastric secretion occurs which is not dependent on the presence of food. Its small volume permits its neutralization by the mucus of the pyloric antrum, swallowed saliva and possibly also regurgitated duodenal contents. Dragstedt[1] suggests that this neutralizing mechanism may fail or prove inadequate and that, as a result, more or less pure gastric juice may accumulate in a stomach empty of food. Artificially induced, continued excessive secretion of gastric juice following implantation of histamine pellets in wax produced ulcers in all the common laboratory animals.

Acting on the concept that the hypersecretion of gastric juice in gastroduodenal ulcer is largely neurogenic, Dragstedt treated a series of patients who were troubled with more or less intractable gastroduodenal ulceration by utilizing an operation designed to remove permanently and as completely as possible the vagus innervation of the stomach. Incomplete vagotomies performed in the past (Weinstein, Winkelstein) have not been followed by a beneficial therapeutic effect. The desirability of a complete vagotomy was indicated by the studies of Hartzell, who demonstrated in dogs that section of both nerves decreases the acidity of the gastric contents. If the section is technically incomplete, the effect is disappointing. Experiments confirming and extending these observations were performed by Dragstedt and his associates on animals with totally isolated stomachs, both with and without vagal innervation.

Thornton, Storer and Dragstedt,[2] in reporting the results of intrathoracic vagotomy on 38 patients with duodenal, gastric or gastrojejunal ulcer, state that the postoperative course indicated complete relief of ulcer symptoms, objective evidence of healing of the ulcers and definite improvement in general health in almost all. The average twelve hour continuous secretion obtained in 8 patients with duodenal ulcers and in 2 patients with gastric ulcers before the vagotomy amounted to 821 cc., and this decreased to 335 cc. after division of the vagus nerves. The free acidity was 47 clinical units before and fell to 15 units after the operation. Histamine stimulation produced an abundant secretion of acid gastric juice in 19 patients thus tested before operation, and there was no diminution either in volume or in free acidity after the vagus section. This lack of response parallels the experiments on animals and is explained by the fact that histamine acts on the peripheral neuroglandular apparatus or directly on the secreting cells and not through the mediation of the vagi. Of 15 patients submitted to the insulin test, 14 were not affected by insulin following vagotomy. A decrease in the gastric tonus and in the frequency and amplitude of the hunger contractions was present in each case.

Excessive, continuous secretion of gastric juice occurs in most patients with gastroduodenal ulcer in the absence of any known type of gastric secretory stimulus. The reduction in this secretion produced by complete division of the vagus nerves to the stomach proves that the hypersecretion is neurogenic in character. The most pronounced and regular departure in these cases from the normal lies in the volume and acidity of the continuous night secretion. This is apt to be especially large in young people with duodenal ulcer who present in varying degree other signs of nervous tension and instability.

Grimson[3] subjected 18 patients with refractory ulcers that had produced serious symptoms during an average time of eleven years to intrathoracic vagotomy. The ulcers healed in several weeks. Twelve hour night secretion volumes were reduced from an average of 946 cc. before operation to an average of 342 cc. after operation. The acidity of the secretion of the fasting stomach was changed from an average p_H of 1.72 before operation to an average of 3.55 afterward. Insulin hypoglycemia produced an average maximum increase of free acid to 105 cc. before operation and to 23 cc. several weeks and several months afterward. Gastrometric examination revealed a remarkable reduction to subnormal of the gastric hypermotility observed before operation.

Fifteen patients were selected by Moore and his associates[4] because of the long duration and intractability of the symptoms of intractable peptic ulcer as well as the past and present complications. All the patients had had one or more rigorous terms of hospital medical treatment. Following transthoracic vagotomy the patients were allowed to eat and drink anything they wished, including alcohol and coffee, since it was believed that the operation would not be put to an adequate test if the patient continued rigid medical therapy. The ulcers of 12 patients have healed or are healing, and all but 1 patient had immediate and sustained symptomatic relief. There have been no surgical complications such as empyema, persistent pneumothorax or cardiospasm. This procedure is particularly applicable, in the opinion of these authors, to patients who have had other surgical interventions, such as pyloroplasty, posterior gastrojejunostomy or gastric resection and who present themselves with renewed ulceration. The largest group in which this procedure seems of value are young or middle aged patients with a long history of peptic ulceration, possibly with previous perforations or hemorrhages, unobstructed and not acutely bleeding, who have been refractory to medical treatment and who have severe ulcer pain in times of stress, which can be relieved transiently by the usual antiacid, milk or food. The operation is contraindicated in acute perforation, acute massive hemorrhage or advanced cicatricial obstruction.

[3] Grimson, K. S., in discussion on preceding paper, p. 769.

[4] Moore, F. D.; Chapman, W. P.; Schulz, M. D., and Jones, C. M.: Transdiaphragmatic Resection of the Vagus Nerves for Peptic Ulcer, New England J. Med. **234**: 241 (Feb. 21) 1946.

The period of observation has been too short to permit a final evaluation of the method, and the question of ultimate regeneration of the divided vagi remains undecided. Such complications as dilatation of the stomach and greatly impaired motility make necessary delay in final conclusions regarding the exact value of the technic.

WATCH THE ANTIVIVISECTIONISTS

State legislators are meeting in 1947 in forty-four states. In some of these legislatures bills will be introduced by the antivivisectionists seeking curtailment of the use of animals in research. The possible crippling of medical progress, medical education, manufacture of pharmaceuticals and standardization of drugs for therapeutic use as a result of their efforts does not concern the antivivisectionists. Unless they are effectively inhibited they may come even more perilously close to success than they did in the legislative session in New York when their dog bill passed one house of the legislature. Only the vigilance of New York physicians and scientists succeeded in stopping them.

The annual report[1] of the National Anti-Vivisection Society, 37 South Wabash Avenue, Chicago, contains a copy of a letter which is being sent to approximately 13,000 state legislators individually typed and signed by Ward Caille, the vice president. Accompanying the letter will be a postcard, return envelop and a copy of a booklet, "The Case Against Vivisection," which is an alleged refutation of a powerful article in *Collier's*,[2] which established beyond doubt the necessity for using animals in research.

In this letter there is the usual medley of misstatements. Claim is made that in the membership of the National Anti-Vivisection Society "there is a percentage of licensed physicians ten times greater than the percentage of physicians in the whole American population, and for reasons they well understand only a few of these doctors deem it wise to allow us the use of their names." This is statistical hocus-pocus which tells exactly nothing; the membership rolls of the National Anti-Vivisection Society have never been open to inspection.

The Anti-Vivisectionists' letter admits that "torture of animals" can exist only by nonenforcement of anticruelty laws but does not explain the persistent reluctance of the antivivisection societies to invoke such laws, nor does it mention the ignominious court reverse sustained by them in Chicago on one of the few occasions when they were unwise enough to venture into prosecution.

The letter pretends "we need to know for our own guidance how legislators as a class feel" and "legislators are second only to doctors in their importance and interest to us." It closes with a request for a personal favor to check the "enclosed card and seal it in the enclosed return envelop. As pointed out above, your signature is entirely optional." Following is a reproduction of the card:

I am (for) (against) the vivisection of animals.

IF "AGAINST," PLEASE GO ON TO CHECK ONE OR MORE OF THE STATEMENTS BELOW

☐ Unfortunately, I would not vote for anti-vivisection legislation now because I feel such action would be premature.

☐ I would support anti-vivisection legislation with my vote, at present, but only with my vote.

☐ I would support anti-vivisection legislation by both my vote and the influence of my publicly expressed opinion.

☐ I would support anti-vivisection legislation by any means, deeming it right and considering it important enough not to be submerged by other political problems.

This is an old dodge in a new dress. It was tried on the medical profession some years ago. Questionnaires sent to physicians resulted in approximately 3,600 replies, which represents just about 5 per cent of the profession. In this 5 per cent would naturally be included all the proponents of the antivivisectionist movement, but even so these constituted only a bare majority of physicians replying. Nevertheless this so-called "poll" has been widely quoted as an indication that doctors favor the activities of the antivivisectionists against medical research.

This legislative poll, it may safely be predicted, will be used as the medical poll was used. No matter how small the number of legislators who reply, the proponents will quite likely constitute a majority, since most recipients of the questionnaire will file it in the wastebasket. The false "majority" thus engineered by questionable statistical practices will be widely publicized as representing the "attitude of legislators" toward antivivisectionists.

---

1. Annual Report, National Anti-Vivisection Society, Dec. 31, 1946.
2. Kirk, N. T., and Ratcliff, J. D.: Mice or Men? Collier's, June 29, 1946.

The antivivisectionists distributed over 2,000,000 pieces of literature in 1946. "Every state in the Union was covered and in some instances entire towns were blanketed." They have lists of dog licenses, and their members send them names copied from local telephone books.

Unless the medical profession and allied scientists and educators are alert we may yet see science humiliated by the enactment of crackbrained legislation.

Current Comment

1,646 SUCCESSFUL VACCINATIONS ON A TROOP SHIP

Ten days out from Suez on a troopship bound for New Zealand,[1] a man was admitted to the hospital with a diagnosis of acute tonsillitis. Two days later a papular rash appeared; on the following day the rash increased with a tendency to coalesce over the face, shoulder, upper arm and other areas. Next day the papules showed gray-white tops; some were umbilicated, and there was further coalescence. The patient now was drowsy and confused. The eruption progressed until only five small areas of clear skin remained through which to pass a hypodermic needle. At a consultation of medical officers on board, on the fifth day, the consensus was that this was a case of smallpox. On the twelfth day the patient died. Vaccination scars were not found on his skin. He had never been successfully vaccinated in the Army. Investigation showed that he had been A. W. O. L. before embarkation and had been picked up in the most doubtful part of an out of bounds area. When smallpox was suspected, all contacts were vaccinated and the ship's company was revaccinated. The amazing result was a total of 1,646 successful vaccinations. Precautions taken to prevent the introduction of smallpox into Australia, where some of the troops disembarked, and into New Zealand apparently were adequate. Palmer states that the population in New Zealand is virtually unprotected. Its medical practitioners, however, fully realize, as physicians do everywhere, that successful vaccination is the only sure means of preventing an outbreak of smallpox. If their fellow countrymen also were convinced, public opinion would force army authorities to see that their soldiers were immunized against this disfiguring and often fatal disease. A few cases of serious and even fatal smallpox occurred in the United States Army during the recent war. These are believed to have been due, however, not to failure to vaccinate but to failure to vaccinate properly and to interpret the results correctly. Now comes a recent report that 820 cases of smallpox occurred in Hong Kong in November and that 530 cases were fatal. Civilians should be urged to have successful vaccination against smallpox. The hazard is especially important for those who travel.

EUPHEMISMS AND EQUIVALENTS IN TEACHING AND PRACTICE

While the education of the public in medical matters is desirable, certain factors inevitably associated with the process produce undesirable effects, particularly in neurotic and suggestible persons. The increasing flow of medical information given to the public through the press and the radio makes persons aware of the seriousness of certain diseases and arouses dread in the apprehensive that they may become victims of some of these conditions. If this leads, as it frequently does, to prompt consultation with a physician when dubious symptoms arise, the effect is highly desirable. Unfortunately, unduly apprehensive people may not be reassured even by a favorable report, and others often fail to consult a physician. The printed page and the radio broadcast are not the only, or even the chief, sources of education of the public in medical matters. The physician, both as practitioner and as teacher, bears a heavy responsibility in this field. The treatment of many diseases is much more efficient when the patient is informed of the underlying principles. However, in the instruction of patients discretion and tact on the part of the physician are essential. The use of terms which are ominous or even terrifying must be avoided. This is best done by the use of euphemisms, which the dictionary defines as "mild or agreeable expressions for something disagreeable." The teacher of medicine, particularly in bedside instruction, is in a position to do considerable harm if he fails to select his language with care. It is customary on teaching rounds and in bedside clinics for a student to recount the history of the patient. If this is not done intelligently a nervous patient may be frightened almost out of his senses. In the subsidiary questioning too both the questions and the answers should avoid terms which are of grave import to the average layman. After the history has been elicited and the pertinent observations have been demonstrated, the diagnosis should not be discussed before the patient. Medical students must be instructed in the principles discussed and must be given a working knowledge of the use of euphemisms and equivalents. Patients with a history of syphilis may be reported as luetics, those having positive Wassermann tests may be described as having positive complement fixation tests. In cases of angina pectoris the disease may be discussed with students in the presence of the patient as stenocardia. Patients with this disease may be told that they are suffering from spasm of the heart arteries or attacks of anoxemia of the heart muscle. In like manner neoplasm, without the qualifying adjective malignant, may be used to describe carcinomas and other growths. Excessive addiction to alcohol may be spoken of as ethylism. These are but a few examples of the many euphemisms or equivalents that may be used. This whole question is bound with the ancient but newly stressed conception of disease as involving not only the soma but the psyche, an idea not usually grasped in its full implication by the medical tyro but borne in on the practitioner with cumulative force as his experience increases.

Washington Letter

(From a Special Correspondent)

Jan. 13, 1947.

President Asks for Broadened Health Program and Social Security

President Truman informed the Republican 80th Congress in his state of the Union message of his labor proposals and desire for cooperation. His legislative plans contained a comprehensive national health program and broadened social security. Mr. Truman also advocated the creation of a Department of Welfare to handle health, education and welfare. "Of all our national resources," he stated, "none is of more basic value than the health of our people. Over a year ago I presented to the Congress my views on a national health program. The Congress acted on several of the recommendations of this program—mental health, the health of mothers and children and hospital construction. I urge the Congress to complete the work begun last year and to enact the most important recommendation of the program—to provide adequate medical care for all who need it, not as charity, but on the basis of payments made by the beneficiaries of the program."

Physician Veterans Want Hospitals to Employ Doctors with Military Service

The Physician Veterans of World War II, known here as the "Docvets," protested to the Surgeons General of the Army and Navy against a deferment policy whereby recent medical graduates can obtain a deferment if they present letters from hospitals saying they have jobs as residents. A spokesman said "We believe such jobs should go to competent physician veterans." Navy Surgeon General Swanson promised that no deferment because of hospital residency would be granted if a physician veteran can take the job. Army Surgeon General Kirk explained that 3,000 medical school graduates whose tuition was paid by the government are available for army service. The Army can't use them now, which is the reason for deferments. The Docvets applauded General Kirk's comment that hospitals should employ veterans rather than younger doctors without military service.

Rh Blood Laboratory Set Up in Capital

Two doctors who served in the Army Medical Corps during the war in laboratory blood testing and blood bank work plan are setting up a central laboratory to make Rh blood available to Washington mothers. They are Dr. Oscar B. Hunter Jr., son of Dr. Oscar B. Hunter, secretary-treasurer of Doctors Hospital and a governor of the new Congress of American Pathology, and Dr. John Ross, son of Charles G. Ross, White House press secretary.

Representative Lemke Revives Bill to Outlaw Vivisection

Representative Lemke, Republican of North Dakota, has reintroduced his bill to outlaw medical experiments on living dogs in the District of Columbia. The measure has been defeated in past sessions. The bill would make it a misdemeanor to experiment or to perform any operation on living dogs except those normally performed for the convenience of the owner and "welfare and curing" of the animal. The bill was referred to the House District Committee.

Health and Welfare Stressed in Economic Report

In his economic report to Congress, President Truman advocated increased old age benefits and survivors' insurance under Social Security and extended aids to the blind and dependent children beyond 1947. The boost in Social Security benefits was asked to meet rising living costs. Also recommended was long range revision of social security laws to increase the amount and duration of unemployment benefits, sickness and disability insurance for workers and partial federal financing of the Social Security system. Mr. Truman said "Health insurance relates clearly to the efficiency of workers and thus to the productivity of industry and agriculture. And this is even true of education, which must be reshaped continuously to meet the changing demands and job opportunities of the machine age or, some day, of the atomic age."

National Health Insurance Law Slated for Consideration by New Congress

Senator Smith, Republican of New Jersey, announced that he would launch a Republican drive for enactment of a national health insurance law early in the new Congress. His plan would provide voluntary participation, with each state to work out its own insurance program for hospital and medical care. He advocates a $200 million federal fund from which aid could be supplied to help low income groups. The proposal differs considerably from the administration's compulsory insurance plan which failed to win enactment at the last session. "We want to give the greatest measure of freedom to the states in setting up their health insurance plans," explained Senator Smith. His bill would create a council to which a state could appeal any dispute over proposed grants-in-aid, which would be on the basis of $2 in federal funds for every $1 paid by the state. Senator Smith is on the committee which will report on a health program for the Senate Republican members.

Swedish Hospital Is Model for Washington's New Hospital Center

W. E. Reynolds, U. S. public buildings administrator, has returned from a European trip with enthusiastic reports about Stockholm's new Soder Hospital, built during the war, which is said to be the only permanent, modern and complete hospital equipped for all specialties of medicine. It has been suggested as a model for the $20 million hospital center. The Stockholm plan, if adopted, would have to be modified to conform to the fact that Emergency, Garfield and Episcopal hospitals, to be merged in the new center, must maintain their identities to preserve endowments and other assets. The Stockholm hospital is municipally owned and has small emergency receiving stations located in large areas. Planes, ambulances, motorboats and trains are used to speed patients needing specialized treatment to large hospitals.

President Comments on Need for Continued Research and Patents

President Truman explained in his Economic Report his recent action to stimulate research, stating "The United States will this year invest more than a billion dollars in research. In order to protect national security and the development of the domestic economy I have established by executive order a presidential research board to survey federal research and development programs. The continuation of a research program of large magnitude for many years to come, together with the fact that many of the inventions resulting from it will be patentable, calls for action to protect the public interest in inventions and discoveries resulting from expenditures of public funds."

National Science Foundation Nearer Reality by Boston Resolution

Advocates of a National Science Foundation believe that this project is nearer realization than ever before as a result of the resolution adopted by the policy council of the American Association for the Advancement of Science in Boston. An intersociety committee was formed to press for legislation to create such a foundation. Dr. Kirtley F. Mather, chairman of the committee, and Dr. Harlow Shapley, new president of the association, stated that the Kilgore-Magnuson bill, passed last year by the Senate only to die in House committee, would be satisfactory if enacted by the 80th Congress. The resolution stated that "the creation of a National Science Foundation to support fundamental scientific research and the education of scientists is of utmost importance for the health, security and welfare of the nation."

Liberated Japan Adopting Startling Program of Eugenics

Copies of the *Nippon Times* of Tokyo of November 6 reaching Washington officials reveal that liberated Japan, through its Population Policy Commission, is about to adopt a program of eugenics which American newspaper commentators say bears resemblance to programs enforced by Hitler. The Japanese plan makes no mention of Nordics or non-Nordics but refers to "qualified" and "unqualified" parents. For the latter, sterilization and compulsory castration are proposed. Another feature "to control births and produce a better race" includes abortion "to protect the health of the mother or for ethical reasons, such as "conception due to rape, error or ignorance."

War Department Seeks Adoption of Universal Military Training

Although President Truman has advocated dropping the word "military" from his proposed program of national youth training, the War Department will endeavor to have this economy minded Congress adopt its program of universal military training. An official statement points out that the whole cost of universal military program for one year would cost less than three days of the second world war, $800 million. The War Department points out that a civilian commission would control the program, which would emphasize physical and religious development.

Dr. Albert F. Woods to Continue Research in Plant Disease Viruses

On his retirement December 31 as educational adviser of the Department of Agriculture, Dr. Albert F. Woods, a veteran of fifty years with the department, plans to resume research into plant disease viruses which he began in 1895. He is working on the theory of William Stanley, discoverer of the tobacco mosaic virus, that such entities are chemical rather than organic. His research would bear on why certain virus diseases do not yield to drugs, as do bacteria. It is pointed out that there is a close link between viruses and certain types of cancer, such as skin cancer.

Creation Urged of Single Department of National Defense

Merger of the armed forces, long contested in Congress, is on the agenda of the 80th Congress for further consideration. President Truman in his message advocated a single Department of National Defense to cut costs and enhance national security. He also appealed for universal training to develop a trained citizens' reserve. The President also called for extension of Selective Service only if the War Department finds that it is necessary to maintain the strength of the army. The War Department is to report in time for Congress to act. Present draft laws expire March 31.

Senator Langer Advocates Maternity Leave for Federal Worker

Senator Langer proposes to introduce a bill granting women who have at least one year's federal service the right to maternity leave of sixty days. The bill is being prepared by officials of the Federal Security Agency and the Women's Bureau of the Department of Labor. A similar bill failed to pass Congress last year.

President Truman Appeals for March of Dimes

President Truman asked for national support of the annual March of Dimes, January 15 to 30, to finance the fight against infantile paralysis. He will broadcast to the nation on the night of January 30, the sixty-fifth birthday anniversary of the late President Roosevelt, founder of the National Foundation for Infantile Paralysis.

Dr. Calvin Klopp Is Director of Cancer Prevention Clinic

The first cancer prevention clinic to be opened in the District of Columbia is in the Warwick Cancer Clinic at Garfield Memorial Hospital, in charge of Dr. Calvin Klopp. Findings indicative of cancer will be reported to the subject's family or physician. Dr. Klopp explains that the clinic "will make periodic examinations of well people who want to find out if they have cancer and don't know it."

Dr. Bush Is 1946 Winner of Hoover Medal

Dr. Vannevar Bush, president of the Carnegie Institution of Washington, has been named 1946 winner of the Hoover Medal, one of the coveted honors of the engineering profession. It is the most recent of the many awards and honorary degrees conferred on him.

Navy Nuclear Scientist Named to Presidental Board

Dr. Philip N. Powers, navy nuclear physicist, has been appointed to President Truman's Scientific Board. He will serve as assistant coordinator of scientific personnel.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Department of Health, Education and Security

Senator Fulbright, Arkansas, for himself and Senator Taft, Ohio, has introduced S. 140, a bill to create an executive department of the government to be known as the Department of Health, Education and Security. This legislation would authorize the appointment by the President of three undersecretaries in the department, an undersecretary for health, an undersecretary for education and an undersecretary for security. The undersecretary for health, the bill provides, must be a doctor of medicine licensed to practice medicine and surgery in one of the states or territories of the United States or in the District of Columbia, and will perform such duties concerning health as may be prescribed by the secretary of the department or required by law.

Department of National Health

Representative Miller, Nebraska, has introduced H. R. 605, a bill to establish a Department of National Health at the head of which shall be the secretary of national health, appointed by the President *by and with the advice and consent of the Senate.* The declared purpose of this legislation is to bring about, so far as practicable, a centralization in the Department of National Health of all activities of the federal government relating to health. The President will be required, as soon as practicable after the enactment of the bill, to transfer by executive order from existing departments, agencies and offices of the government, to the Department of National Health, such agencies and functions as he may determine to be appropriate to carry out the declared purpose.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 10-11. Dr. Victor Johnson, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Orthopedic Surgeons, Chicago, Jan. 25-30. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.

Central Surgical Association, Chicago, Feb. 20-22. Dr. Walter G. Maddock, 250 East Superior St., Chicago, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24-27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

GOVERNMENT SERVICES

ARMY

406th MEDICAL GENERAL LABORATORY IN TOKYO

One of the organizations that assist in safeguarding the health of our occupation forces in Japan is the 406th Medical General Laboratory in Tokyo, which has now been fully staffed and equipped with 20 medical officers, 50 enlisted men, 5 Japanese doctors and 40 Japanese laboratory technicians and helpers. Field teams traveling about Japan in special laboratory cars gather scientific data, which are correlated and interpreted by the laboratory. Some field teams, for example, collect specimens of blood from people and animals in representative areas, as a basis of comparison and further study, in case an outbreak of Japanese B encephalitis should occur. One of the larger projects the laboratory has taken over is the research begun by the Commission on Virus and Rickettsial Diseases on B encephalitis. The laboratory does such routine procedures as examination of surgical tissue removed at operation and various kinds of blood tests. About 5,000 white mice are used each week in the various tests and experimental work. The laboratory analyzes daily the water supply in the Tokyo-Yokohama area and examines certain food products, such as ice cream, used by soldiers throughout Japan. Most of the routine testing of foods and drugs consumed by Allied personnel is carried out in this army installation, which is the only one of its type in Japan. The commanding officer of the laboratory is Lieut. Col. W. D. Tiggertt.

MEDICAL OFFICERS ATTENDING VENEREOLOGY CLASSES

Major Gen. Norman T. Kirk, the Surgeon General, announces that sixteen selected officers of the Army Medical Department have enrolled in the first postwar classes in venereology at a civilian institution opened in December at the University of Pennsylvania. Such courses have become necessary, General Kirk said, to replace those venereal disease specialists who are being separated from the service, and while this abbreviated course "will not give us specialists in venereal disease management, it will be a step in the right direction." These sixteen officers will study at the Institute for the Study of Venereal Disease at the University of Pennsylvania and at the conclusion of the course will return to their stations in army general hospitals. The course is conducted by Dr. John H. Stokes, director of the institute and medical consultant to the Secretary of War through the Surgeon General.

Another class is scheduled to open in January at the University of Southern California, Los Angeles.

ARMY MEDICAL LIBRARY

A permanent office for the Association of Honorary Consultants to the Army Medical Library has been opened in room 26, Library of Congress, Washington, D. C., where all matter pertaining to the association should be sent.

Mr. Scott Adams, formerly chief of the acquisition division of the library, has been appointed acting librarian to replace Mr. Wyllis Wright, who is leaving to become librarian of Williams College, Williamstown, Mass.

CONFERENCE ON VENEREAL DISEASE CONTROL

At a conference on venereal disease control at the New Grand Hotel, Yokohama, Japan, Dec. 4, 1946 opening remarks were presented by Lieut. Gen. Robert L. Eichelberger, commanding general, Eighth Army, and Col. Philip L. Cook, M. C., surgeon, Eighth Army. Col. G. N. Schuhmann, M. C., also of headquarters, Eighth Army, outlined the purpose of the conference. Lieut. Col. J. S. Smith, Inf., commanding officer West Camp, Kobe Base, discussed development of the hospital annex and the method of venereal disease control in use at the base, and Capt. J. E. Harroun, M. C., Surgeon's Office, Yobas, studies of venereal disease in Yobas. Other speakers were Lieut. A. H. Randelman, M. C., venereal disease control officer, and Dr. O. M. Elkins, consultant in venereal disease control, G.Hq. S. C. A. P.

VETERANS ADMINISTRATION

OSTEOPATHS TO SERVE IN VETERANS ADMINISTRATION

The Veterans Administration, Washington, D. C., announces that arrangments have been completed for the appointment of doctors of osteopathy to serve in the Veterans Administration, department of medicine and surgery. The appointments will be made in compliance with Public Law 293 (79th Congress), which authorizes the Veterans Administration to hire doctors of osteopathy to work with veterans. To be eligible a doctor of osteopathy must be a citizen of the United States, hold a degree of osteopathy from a college or university recognized by the Veterans Administration, hold a license to practice osteopathy in one of the states, territories or the District of Columbia, have completed an internship satisfactory to the Veterans Administration, and meet prescribed physical standards.

RESIDENCY TRAINING IN NEUROLOGY

Additional residency training programs for Veterans Administration physicians interested in neurology have been organized. The residencies, which will vary from one to three years, are designed to prepare residents for certification in neurology by the American Board of Psychiatry and Neurology.

One training program will be conducted under the joint auspices of Boston University, Tufts Medical College and Harvard University. Residents will be stationed at the Veterans Administration hospital at Framingham, Mass., which has special units for the study of epilepsy, aphasia, paraplegia and electroencephalography and a complete diagnostic neurologic service. Applications should be sent to Dr. Harry C. Solomon, chairman, Deans Subcommittee for Neuropsychiatry, Harvard Medical School, Boston.

The other training program will be conducted at Jefferson Medical College and Clinic, Philadelphia, under the auspices of the Veterans Administration Philadelphia Deans Committee. Dr. Bernard J. Alpers, professor of neurology at the Jefferson Medical College, will direct the program. Applications should be sent to Dr. Edward A. Strecker, chairman, Deans Subcommittee for Neuropsychiatry, University of Pennsylvania School of Medicine, Philadelphia.

Other medical schools affiliated with the Veterans Administration for residency training in neurology where training programs are already under way, are:

Medical School	VA Hospitals and Clinics	Applications Received by
Cornell University Columbia University	Bronx, N. Y. Hospital	Dean Willard C. Rappleye, 630 W. 168th St., New York
Northwestern University University of Illinois	Hines, Ill., Hospital	Dr. Lewis J. Pollock, Northwestern University, Chicago
University of Minnesota	Minneapolis	Dean Harold S. Diehl, University of Minnesota

PUBLIC HEALTH SERVICE

ORGANIZATION FOR NATIONWIDE MEDICAL RESEARCH

The Congress of the United States has designated the National Advisory Health Council, the National Advisory Cancer Council and the National Advisory Mental Health Council to make recommendations to the Surgeon General, U. S. Public Health Service, regarding means necessary to carry out his responsibilities (Public Law 410 section 301, 78th Congress, and Public Law 487, section 7, 79th Congress) with respect to the use of funds for research. In order to provide these advisory councils with expert advice on applications for research grants, the Public Health Service has organized nineteen special study sections, consisting mostly of civilian scientists, in surgery, pathology, public health methods, pharmacology, tropical diseases, antibiotics, bacteriology, biochemistry and nutrition, cardiovascular diseases, gerontology, hematology, malaria, metabolism and endocrinology, physiology, radiobiology, sanitation, syphilis, virus and rickettsial diseases and dental subjects.

Research projects approved by these councils will receive grants in aid. Applications for grants may be made by schools of medicine, hospitals, public or private institutions and individuals. The plan inaugurated by the Public Health Service calls for complete academic freedom and unrestricted opportunity to carry on productive research.

At a recent meeting of the study Section on Metabolism and Endocrinology, Dr. Joseph H. Barach of the University of Pittsburgh was elected chairman. The other members of this section are:

Dr. Charles H. Best, University of Toronto.
Dr. Jerome Conn, University of Michigan.
Dr. Herbert M. Evans, University of California.
Dr. Roy Hertz, National Institute of Health, Washington, D. C.
Dr. F. D. W. Lukens, University of Pennsylvania.
Capt. W. F. Loftin, United States Navy.
Dr. Alexander Marble, Baker Clinic, Boston.
Col. Charles R. Mueller, United States Army.
Dr. Henry B. Mulholland, University of Virginia.
Dr. Lester J. Palmer, Mason Clinic, Seattle.
Dr. Elaine P. Ralli, New York University.
Dr. Henry T. Ricketts, University of Chicago.
Dr. Randall G. Sprague, Mayo Clinic, Rochester, Minn.
Dr. Cecil Striker, Cincinnati.
Dr. Hugh L. C. Wilkerson, executive secretary, U. S. Public Health Service, Washington, D. C.

STATE AGENCIES TO ADMINISTER HILL-BURTON ACT

Forty-three states and territories have designated agencies to administer the Hospital Survey and Construction Act. According to the U. S. Public Health Service, communities, hospitals and professional groups wishing to participate in the program should direct their inquiries to the appropriate state or territorial agency named in the following list:

Alaska	Territorial Department of Health, Juneau	Dr. C. Earl Albrecht Commissioner of Health
Arizona	State Department of Health Phoenix	Dr. G. F. Manning Supt. of Public Health
Arkansas	State Board of Health Little Rock	Dr. T. T. Ross State Health Officer
California	State Dept. of Public Health San Francisco	Dr. Wilton L. Halverson Director of Public Health
Connecticut	State Department of Health Hartford	Dr. Stanley H. Osborn Commissioner of Health
District of Columbia	D. C. Health Department Washington	Dr. George C. Ruhland District Health Officer
Florida	Florida State Improvement Commission, City Administration Building, Tallahassee	Mr. C. H. Overman Director
Georgia	Georgia Department of Public Health, Atlanta	Dr. T. F. Abercrombie Director of Public Health
Hawaii	Territorial Board of Health Honolulu	Dr. C. L. Wilbar, Jr. President, Board of Health
Idaho	Idaho Dept. of Public Health, Boise	Mr. L. J. Peterson, Acting Administrative Director
Illinois	State Dept. of Public Health, Springfield	Dr. Roland H. Cross Director of Public Health
Indiana	State Board of Health Indianapolis	Dr. Lee E. Burney State Health Commissioner
Iowa	State Dept. of Health Des Moines	Dr. Walter L. Bierring State Comr. of Health
Kansas	State Board of Health Topeka	Dr. F. C. Beelman Sec. & Executive Officer
Kentucky	State Department of Health Louisville	Dr. P. E. Blackerby State Health Commissioner
Louisiana	Health & Hospital Division of the Governor Baton Rouge	Mr. Charles Mitchell Director
Maine	Department of Health and Welfare, State Bureau of Health, Augusta	Dr. Leverett D. Bristol Commissioner of Health and Welfare
Maryland	Maryland State Planning Comm., 104 Equitable Building, Baltimore	Mr. I. Alvin Pasarew Director Mr. Henry P. Irr, Chrmn.
Massachusetts	Mass. Dept. of Public Health, Boston	Dr. Vlado A. Getting, Commissioner of Public Health
Minnesota	Minn. Dept. of Health St. Paul	Dr. A. J. Chesley, Secretary & Executive Officer
Mississippi	Miss. Commission on Hospital Care, 207 Tower Building, Jackson	Dr. D. V. Galloway Executive Director
Missouri	State Division of Health, Bureau of Public Health & Welfare	Dr. R. M. James Director, State Div. of Health
Nebraska	Nebraska Dept. of Health Lincoln	Dr. W. S. Petty Director of Health
Nevada	State Dept. of Health Carson City	Dr. Fred S. Loe State Health Officer
New Jersey	New Jersey State Dept. of Institutions & Agencies Trenton	Mr. Sanford Bates Commissioner
New Mexico	New Mexico Dept. of Public Health, Santa Fe	Dr. James R. Scott Director of Health
New York	New York State Postwar Public Works Planning Commission, New York	Mr. John E. Burton Chairman
North Carolina	N. C. Medical Care Commission P. O. Box 1880 613-615 Commercial Bldg. Raleigh	Mr. James H. Clark Chairman
North Dakota	State Dept. of Health Bismarck	Dr. William M. Smith Acting State Health Officer
Ohio	Ohio Dept. of Health Columbus	Dr. Roger E. Heering State Director of Health
Oklahoma	State Health Department 3400 North Eastern Oklahoma City	Dr. Grady F. Mathews Commissioner of Health
Oregon	State Board of Health Portland	Dr. Harold M. Erickson State Health Officer
Pennsylvania	State Dept. of Welfare Harrisburg	Miss S. M. R. O'Hara Sec. of Welfare
Puerto Rico	Dept. of Health San Juan	Dr. Juan A. Pons Commissioner of Health
South Carolina	State Research, Planning & Development Board Columbus	Mr. Robert M. Cooper Director
South Dakota	State Board of Health Pierre	Dr. Gilbert Cottam, Sup't., State Board of Health
Tennessee	Tennessee Dept. of Public Health, Nashville	Dr. R. H. Hutcheson, Commissioner of Public Health
Texas	State Department of Health Austin	Dr. George W. Cox State Health Officer
Utah	State Department of Health Salt Lake City	Dr. William M. McKay State Health Commissioner
Virginia	Virginia Dept. of Health Richmond	Dr. L. J. Roper State Health Commissioner
Washington	State Dept. of Health Seattle	Dr. Arthur L. Ringle State Director of Health
West Virginia	State Dept. of Health Charleston	Dr. N. H. Dyer State Health Commissioner
Wisconsin	State Board of Health Madison	Dr. Carl N. Neupert State Health Officer

CONFERENCE ON GASTRIC CANCER

The Surgeon General of the U. S. Public Health Service announced a conference held at Billings Hospital, University of Chicago, Dec. 5 and 6, 1946, arranged by the Gastric Cancer Committee of the National Advisory Cancer Council. This was the third large conference on gastric cancer sponsored by the council; the first was held in 1940 at the National Institute of Health, Washington, D. C. The recent conference stressed particularly cancer of the gastrointestinal tract. Speakers were present from various parts of the United States. The chairman of the Gastric Cancer Committee of the National Advisory Cancer Council is Dr. George M. Smith, Yale University, New Haven, Conn. The other members of the committee are Dr. Shields Warren, New England Deaconess Hospital, Boston; Dr. Owen Wangensteen, University of Minnesota, Minneapolis; Dr. Alexander Brunschwig, University of Chicago; Dr. Leonell C. Strong, Yale University; Dr. George T. Pack, Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York; Dr. A. C. Ivy, University of Illinois Medical School, Chicago; Dr. Sherwood Moore, Director, Mallinckrodt Institute of Radiology, St. Louis, and Dr. Mandred W. Comfort, Mayo Clinic, Rochester, Minn.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ARIZONA

Arnold B. Kurlander Leaves State Health Department.—Dr. Arnold B. Kurlander, Phoenix, for more than a year director of the mass chest x-ray program of the state department of health's division of tuberculosis control, left recently for Ohio, where he will activate a similar program. Lent to the state by the U. S. Public Health Service, he is credited with doing much to make the people of Arizona conscious of their greatest health problem—tuberculosis. Principal objectives of the survey have been, first, to discover early cases of tuberculosis so that they may be brought under proper medical care and supervision during the most infectious stage of the disease; second, to discover "hidden" cases and assist in their isolation and, third, to educate the people in the problem of tuberculosis. Since late in 1945, when the program began, 108,000 x-ray pictures have been taken, 1,500 of which showed evidence of reinfection pulmonary tuberculosis. The mobile x-ray unit has operated in every county except three, which will be covered in a new series of surveys begun in January of this year.

CALIFORNIA

Herrick Memorial Hospital.—To honor Dr. LeRoy Francis Herrick, who founded the Berkeley Hospital in 1904 and conducted it for twenty-eight years and whose fortune was donated to this community nonprofit enterprise, the board of directors recently dedicated the institution to the founder and named it the Herrick Memorial Hospital. The new $750,000 hospital addition now being completed was financed by a grant and loan from the federal government and is being equipped through contributions and loans from members of the medical staff and friends of the hospital.

Premarital Blood Test Regulations Amended.—The state board of health has amended its regulations, so that hereafter laboratories will not be approved to do antepartum and premarital tests "if they advertise the performance of these tests in magazines, newspapers, directories, circulars, etc., commonly read by the lay public." Laboratories must also submit to check tests and stipulation of the kind of license which must be held by a person who performs antepartum and premarital tests must be made. The new regulations will soon be ready for distribution, according to *California's Health*, a publication of the state department of health.

Midwinter Conferences of Ophthalmology and Otolaryngology.—Guest speakers at the annual midwinter postgraduate clinical conference in ophthalmology and otolaryngology in Los Angeles, January 20-31, sponsored by the Research Study Club, include Drs. Luzius von Rüedi, Bern Switzerland; Sam E. Roberts, Kansas City, Mo.; Samuel Salinger, Chicago; Ben H. Senturia, St. Louis; William L. Benedict, Mayo Clinic, Rochester, Minn.; Henry P. Wagener, Mayo Clinic, Rochester, Minn.; Kenneth C. Swan, Portland, Ore.; David O. Harrington, San Francisco; Dohrmann K. Pischel, San Francisco, and Meyer Wiener, Coronado, Calif.

ILLINOIS

University News.—Gifts and research grants totaling $122,713 have been made to the University of Illinois—$20,000 of which is for the visual education fund of the College of Medicine in Chicago and $16,000 for research in allergy.

Alienists Hold Postgraduate Conference.—Under the auspices of the Division of Alienists, State of Illinois, there will be a two day postgraduate conference in neuropsychiatry at the Lincoln State School and Colony, Lincoln, January 28-29. The speaker of the evening meeting January 28 will be Dr. Anton J. Carlson, emeritus professor of physiology, University of Chicago, whose subject will be "Can research in our state hospitals contribute to the understanding of the causes of alcohol addiction?" Other well known professors and doctors of Illinois will address the sessions.

Illinois Bacteriologists.—At the winter meeting of the Society of Illinois Bacteriologists January 17 Kenneth B. Raper, Ph.D., Peoria, spoke on "Variation in Molds—Natural and Induced." Drs. Katherine E. Hite, H. Close Hesseltine and Louis Goldstein, University of Chicago College of Medicine, presented "A Study of the Bacterial Flora of the Normal and Pathological Vagina and Uterus." Albert Milzer, Ph.D., Chester Byrd and Dr. Sidney O. Levinson, Chicago, reported "The Use of Autolyzed Brain to Facilitate Transmission of Poliomyelitis to Mice." "Factors Influencing the Stability of Influenza Virus" was under discussion by George F. Forster, Ph.D., Venus Love, B.S., and Esther Carson, D.D.S., Illinois Department of Public Health.

Chicago

The Hektoen Lecture.—The twenty-third Ludvig Hektoen Lecture of the Frank Billings Foundation will be delivered at the Palmer House Friday, March 28, at 8 p. m. by Dr. Herbert M. Evans, director, Institute of Experimental Biology, University of California, on "The Internal Secretions of the Pituitary Body."

Personal.—Dr. Lester R. Dragstedt, professor of surgery, University of Chicago School of Medicine, addressed the Baltimore City Medical Society, Baltimore, Dec. 6, 1946 on "Section of the Vagus Nerves to the Stomach in the Treatment of Peptic Ulcer."——Albert Milzer, Ph.D., formerly research virologist of the Samuel Deutsch Serum Center, Chicago, has been appointed director of the department of bacteriology, Michael Reese Hospital, Chicago, to succeed Dr. Katharine M. Howell, who retired Dec. 31, 1946.

Institute of Medicine Elects Officers.—The Institute of Medicine of Chicago has announced that Drs. Joseph L. Baer has been elected president for 1947; William H. Welker, vice president; George H. Coleman, secretary, and Grant H. Laing, treasurer. Dr. William F. Petersen is chairman of the board of governors, and Drs. Joseph L. Baer, Warren H. Cole and LeRoy H. Sloan have been elected governors for terms of five years. Drs. Stanley Gibson and J. Roscoe Miller have been elected to the unexpired terms of Drs. Ludvig Hektoen and James B. Herrick, who because of age have resigned as members of the board after thirty-one years of continuous and exceptional service.

INDIANA

Changes in Health Officers.—Dr. Charles M. Gibbs recently resigned as Greenfield city health officer after serving many years. His successor will be Dr. R. E. Kinneman, Greenfield.

Countywide Immunization.—Through the county medical society free immunization service has been offered to school children throughout the city of Columbus and Bartholomew County in relation to diphtheria, whooping cough and smallpox.

Acting Medical Director of University Medical Center.—Dr. Donald J. Caseley was recently appointed acting medical director of the Indiana University Medical Center, succeeding Dr. John D. Van Nuys. Dr. Caseley, a native of Sullivan, Ill., received his A.B. degree from DePauw University in 1933 and a medical degree from Indiana University School of Medicine in 1937. He interned at Indianapolis City Hospital. He also served as an orthopedic surgeon in the Army Medical Corps in the recent war.

KENTUCKY

Personal.—Dr. Milus L. Gunn, Harlan, has left for India to do specialized study in the Church Missionary Society of England Hospital, Shikapur, India, located near the Iranian border.

Eight Scholarships Established.—Eight scholarships of $2,000 each have been established for the $100,000 Medical Scholarship Fund for medical students who agree to practice in rural districts of Kentucky after graduation. The scholarships will be administered by the trustees of the fund for the Kentucky State Medical Association and the University of Louisville School of Medicine. According to H. Fred Willkie, Louisville, chairman of the General Fund Committee, Dr. Omer Forest Hume, Richmond, donated the first scholarship. Dr. Hume graduated from the medical department of the University of Louisville in 1917. The Dr. Van A. Stilley Memorial Scholarship has been set up by his heirs. The late Dr. Stilley served as field director for the state department of health in western Kentucky and was president of the state medical association in 1943. The Houston Memorial Scholarship has been granted by Mrs. Jesse Houston Roane, Drs. Hugh L. Houston and Hal E. Houston, Murray, in memory of their father, the late Dr. Edward Brent Houston, one of the leading physicians of Calloway County for thirty years. The scholarship is to be awarded to a premedical student of high standing from Murray State College. Dr. Carl Clifford Howard, Glasgow, present counselor of the association and chairman of the board of trustees of the Medical Scholarship Fund, has presented the Howard Clinic Scholarship. A scholarship was granted by Dr. Gaithel L. Simpson, Greenville, member of the state board of health and board of trustees of the scholarship fund.

Three scholarships of $2,000 each honoring Dr. Charles W. Jefferson, Louisville, have been set up at the University of Louisville School of Medicine by Joseph E. Seagram and Sons Company, distillers, which Dr. Jefferson serves as physician. The Dr. Charles W. Jefferson Scholarship for Surgery was donated by H. Fred Willkie, vice president of the company, and Mrs. Willkie. The Charles W. Jefferson Industrial Medicine Scholarship was raised by employees from cafeteria funds and recreational programs. The Charles W. Jefferson Scholarship for Rural Medicine was established by the company. About one third of the total fund has been subscribed. The revolving Medical Scholarship Fund, launched Dec. 12, 1945, was set up originally as a revolving fund of $50,000 to $75,000 (The Journal, Jan. 19, 1046, p. 162), and the first scholarship was awarded last spring. The trustees of the fund are Drs. John W. Moore, dean, University of Louisville School of Medicine; Gaithel L. Simpson, Greenville; Carl Norfleet, Somerset; Philip E. Blackerbey, Louisville; Senator Cass Walden, Edmonton; Joe Betts, Louisville *Courier-Journal;* Russell Dyche, London, and Mrs. Charles Shelton, Louisville.

MARYLAND

Dr. Victor F. Cullen Retires.—A dinner in his honor in Baltimore December 31 marked the retirement of Dr. Victor F. Cullen as superintendent of all Maryland tuberculosis sanatoriums. Dr. Cullen graduated from Johns Hopkins University Medical School and while an intern at St. Joseph's Hospital is said to have developed tuberculosis. After two years of care and treatment in a sanatorium he returned to Maryland. According to the governor, Dr. Cullen is "the father of modern tuberculosis work in Maryland." He is also a past president of the National Tuberculosis Association.

NEW JERSEY

New Orthopedic Society.—At a recent meeting in Long Branch the New Jersey Orthopedic Society with nineteen founder members elected Drs. Leopold Szerlip, Newark, president, Harold W. Smith, Orange, vice president, and Raphael R. Goldenberg, Paterson, secretary-treasurer.

Academy of Medicine.—Dr. Stewart G. Wolf Jr., assistant professor of Medicine, Cornell University Medical College, New York, will give an illustrated lecture before the Academy of Medicine of Northern New Jersey January 23 on "Changes in Gastric Function Associated with Varying Emotional States and Life Situations."

NEW YORK

Society News.—Dr. Merton C. Hatch, associate professor of clinical obstetrics, Syracuse University College of Medicine, January 9 addressed the Jefferson County Medical Society on "Prenatal and Postpartum Care."

Qualifications for Local Health Officers Revised.—The state sanitary code relating to the qualifications of grade I local health officers has been amended and became effective in December 1946. Previous grade I requirements are retained as grade I-A but apply only to health officers of cities and counties having a population of more than 100,000. Qualifications prescribed for grade I-B are somewhat lower than former grade I qualifications. Previous requirement of four years' full time experience is reduced to three years and, in the case of combined full time experience and scholastic training, the amount of experience is reduced from two years to one year. Local health officers of cities having a population of 50,000 to 100,000 and health commissioners of counties having a population of 100,000 or less must possess grade I-B qualifications. Qualifications for grade II health officers of all towns, villages, consolidated health districts and cities having less than 50,000 population remain unchanged. According to revised requirements, deputy health officers acting temporarily as health officers during the absence or disability of the health officer must possess the qualifications of a grade I-B health officer; part time, those of a grade II health officer. Amendments to the code followed a study by a special committee appointed by the public health council.

New York City

Institute of Oral Pathology.—Dr. Lloyd F. Carver, New York City, will read a paper entitled "Lymphomas and Leukemias and Their Oral Manifestations" at the monthly conference of the New York Institute of Clinical Oral Pathology at the New York Academy of Medicine, January 27, 9 p. m.

Academy Centennial.—In his inaugural address before the New York Academy of Medicine January 2, Dr. George Baehr, president, announced the centenary celebration of the academy which is to be inaugurated with a dinner at the Waldorf-Astoria Hotel March 6. Dr. John A. Ryle, formerly regius professor of physic, University of Cambridge, England, and now head of the Institute of Social Medicine, Oxford, will be the speaker.

Dr. Jarcho Honored.—Dr. Julius Jarcho, obstetrician and gynecologist, was recently honored on his retirement as president of the medical board of Sydenham Hospital at a dinner at which the hospital medical library was formally named the Dr. Julius Jarcho Library. Dr. Jarcho has served as president of the medical board during the last ten years of the forty that he has been associated with the hospital. He graduated from Columbia University College of Physicians and Surgeons in 1904.

Lectures on Venereal Diseases.—A series of free lectures for practicing physicians on diagnosis and treatment of venereal diseases have been planned by the department of health bureau of social hygiene. Meetings are held at the health department building every Saturday morning at 10:30 and will continue through April 26. Experts in special fields of venereal disease control are participating in seminars. On January 25 Dr. Leslie P. Barker, assistant professor of dermatology and syphilology, Columbia University College of Physicians and Surgeons, will discuss "Primary and Secondary Syphilis: Cutaneous Aspects and Differential Diagnosis and Treatment."

SOUTH CAROLINA

Personal.—Dr. John F. Busch, Columbia, was recently appointed assistant chief of the tuberculosis division of the department of medicine and surgery for the Veterans Administration in five Southeastern states. For the past two years Dr. Busch has been medical director of the South Carolina Tuberculosis Association.

Portrait of Dr. Boyd.—Friends and patients of Dr. William A. Boyd, Columbia, recently presented a portrait of Dr. Boyd to Columbia Hospital. The presentation address was given by Dr. Bruce Gill, emeritus professor of orthopedic surgery, University of Pennsylvania. The meeting was attended by physicians and friends of Dr. Boyd from various parts of the country.

County Society Honors Veterans. — The Greenville County Medical Society held a banquet December 2 to honor forty-four returned veterans and one member, John Dendy McBrearty, who gave his life in the service. Each veteran was given a framed scroll attesting appreciation of his efforts in World War II. A bronze plaque was unveiled to the memory of Dr. McBrearty.

TENNESSEE

Society Elections.—Dr. John C. Burch, Nashville, Tenn., *gynecologist, has been elected president of the Nashville* Academy of Medicine and Davidson County Medical Society, succeeding Dr. George Carpenter, Vanderbilt University.—— Dr. W. J. Johnson, Pulaski, Tenn., was named president of the Middle Tennessee Medical Association at its semiannual meeting. Dr. Clarence S. Thomas, Nashville, was chosen vice president and Dr. Carl N. Gessler, Nashville, secretary-treasurer.

WEST VIRGINIA

Practical Nurse Symposium.—Sponsored by the state medical society, state nurses association and the state hospital association, a symposium on the training and service of practical nurses was held Dec. 10, 1946 at Charleston. A resolution was adopted recommending that a survey be made early in 1947 to ascertain the number of women between the ages of 18 and 50 who might be interested in a one year course in practical nursing and that such a course be developed as rapidly as interest warrants. In another resolution it was suggested that the proper officials inaugurate a refresher course without delay for practical nurses who can show evidence that they have satisfactorily worked as practical nurses within the state for the past year. Addresses were delivered by W. T. Sanger, Ph.D., Richmond, Va., president of the Medical College of Virginia; Miss Cecile Covell, R.N., nursing director Neurological Center, Presbyterian Center, New York City; Miss

Nettie Yowell, state supervisor, vocational training for women, state department of education, and Miss Hilda Torrop, R.N., president of the National Association of Practical Nurses. Miss Martha Wooddell, R.N., Clarksburg, presided at the meeting.

GENERAL

Death of Miss Beard.—Miss Mary Beard, Westport, Conn., former director of the American Red Cross Nursing Service and founder of the National Organization of Public Health Nursing, died Dec. 5, 1946 at the age of 70. Miss Beard served the Red Cross during both world wars. She wrote the book "The Nurse in Public Health." Miss Beard resigned her post in the Red Cross Nursing Service in August 1944.

American Board Examination.—The next examination of the American Board of Phychiatry and Neurology for certification in neurology and psychiatry has been tentatively set for May 15-17 in Philadelphia. Applications should be in the hands of the secretary, Dr. F. J. Braceland, 102-110 Second Avenue S.W., Rochester, Minn., ninety days before the examination is scheduled. The last possible date for filing is March 1.

Smallpox.—*Public Health Reports* for Dec. 27, 1946 summarizes the reports of smallpox cases received from various countries through January-September of that year. It is interesting in connection with the current comment concerning smallpox in this issue of The Journal that some cases of smallpox were reported from at least eighty-nine countries. The number of cases reported during that period varied from 1 each in some countries to 57,378 cases in India.

Facts About Nursing.—The Nursing Information Bureau of the American Nurses Association has prepared a booklet called "Facts About Nursing, 1946," which is a complete handbook of statistics covering every possible phase of activity in the nursing profession. Here are the data concerning the size of the profession, distribution of nurses, institutions for the education of nurses, the various fields of specialization and opportunities for employment and advancement. The pamphlet is available from the Nursing Information Bureau at 1790 Broadway, New York 19, at the price of 35 cents.

American Association for the Advancement of Science.—Twenty-six papers in a symposium on "The Rickettsial Diseases of Man" were presented before the medical sciences section of the American Association for the Advancement of Science, which met in Boston Dec. 26, 1946. Some of the other papers were on epidemic typhus, Q fever and tsutsugamushi disease. Charles F. Kettering, D.Sc., director of the research laboratories, General Motors Corporation, delivered the retiring president's address on the future of science. President James Bryant Conant of Harvard University is the incoming president of the association.

Narcotic Violations.—The Bureau of Narcotics reports that Dr. W. D. Maag, Jeffersonville, Ohio, pleaded guilty at Columbus, Ohio, to violation of the federal narcotic law and on Nov. 25, 1946 was sentenced to a term of three years.——Dr. Harry Alonzo K. Hill, Laverne, Okla., pleaded guilty to violation of section 2554(a) of the Internal Revenue Code in the U. S. District Court at Oklahoma City, Okla., and on Nov. 20, 1946 his sentence of five years was suspended and he was placed on probation for a like period. He was also fined the sum of $500, according to an announcement from the Bureau of Narcotics, Washington, D. C.

Essay Contest.—The seventh annual essay contest of the Mississippi Valley Medical Society offers for 1947 a cash prize of $100, a gold medal and a certificate of award for the best unpublished essay on a subject of medical interest and practical value to the general practitioner of medicine. Contestants must be members of the American Medical Association who are residents of the United States. The winner will present his contribution before the Mississippi Medical Society in October. Manuscripts must be received not later than May 1. Further details may be secured from Dr. Harold Swanberg, secretary, Mississippi Valley Medical Society, 209-224 W. C. U. Building, Quincy, Ill.

Seeing Eye Dog Hoax.—Unfounded reports continue to circulate that a blind person can obtain a Seeing Eye dog by collecting quantities of tinfoil, empty paper match folders, cigaret packages or similar articles, warns Edward L. Greene, general manager of the National Better Business Bureau. These stupid rumors, Mr. Greene states, still gather in new victims despite unceasing work to stamp out the hoax by the press, the Better Business Bureaus and the commercial companies innocently involved; and scores of blind persons have saved thousands of useless articles, some with the help of their entire community, only to find that their work was in vain. The Seeing Eye of Morristown, N. J., has repeatedly stated that blind persons desiring a dog should write directly to the organization for particulars.

Society for Study of Sterility.—The first annual conference for the Western Branch of the American Society for the Study of Sterility will be held in Los Angeles February 7-8 to discuss advances in the management of the barren marriage, with particular reference to clinical applications. Topics to be discussed include the social aspects of infertility, role of the hypothalamus, nutritional deficiencies, management of habitual and threatened abortion, physiology of spermatogenesis, the control of ovarian activity, hyalouronidase, semen evaluation, testicular biopsy and hormonal assays. Among the speakers are Drs. Benjamin B. Weinstein, Tulane University School of Medicine, and Carlos D. Guerrero, Mexico City. Further information may be secured from Dr. A. R. Abarbanel, Secretary Program Committee, 441 South Beverly Drive, Beverly Hills, Calif.

Professor Whitby Returns to England.—Sir Lionel Whitby, regius professor of physic, University of Cambridge Department of Medicine and honorary consulting hematologist to the Royal Army Medical Corps, returned to England November 29, having been in this country since October 21. During his stay in the United States he delivered the Hunter Memorial Lecture at the Peter Bent Brigham Hospital, Boston; the Eastman Memorial Lecture at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., and the A. C. Helmholz Lecture at the University of Wisconsin Medical School, Madison. He was also guest lecturer at Western Reserve University School of Medicine, Cleveland; Ohio State University College of Medicine, Columbus; the University of Michigan, Ann Arbor; the Chicago Institute of Medicine, and the State University of Iowa College of Medicine, Iowa City. Sir Lionel, who is said to have been the first physician to apply sulfapyridine to clinical practice, is well known as the co-author of a textbook on hematology.

Nobel Prize Winners in 1946.—At a ceremony in Stockholm, Dec. 10, 1946, King Gustav of Sweden awarded the Nobel Prize in Medicine and Physiology to Herman Joseph Muller, Ph.D., professor of zoology at Indiana University, Bloomington, Ind., and formerly professor of biology at Amherst College, Amherst, Mass., for his research in genetics. The award in chemistry was shared by three men, one half going to James Batcheller Sumner, Ph.D., professor of chemistry at Cornell University, Ithaca, N. Y., for his research on enzymes; the other half was awarded jointly to John Howard Northrop, Ph.D., and Wendell M. Stanley, Ph.D., of the Rockefeller Institute, Princeton, N. J., for their research on virus proteins. The Nobel prize in physics was awarded to Percy Williams Bridgman, Ph.D., formerly professor of physics, Harvard University, Cambridge, Mass., and since 1926 professor of mathematics and natural philosophy, for his research on atmospheric pressure. About 500 persons, including the entire royal family, witnessed the ceremony in the Concert House and attended the prize dinner in the Town Hall. Each of the Nobel prizes was worth $34,000.

Special Society Elections.—At the recent annual convention of the American Academy of Dermatology and Syphilology, Dr. Edward A. Oliver, Chicago, professor of dermatology at Northwestern University, was elected president.——Dr. E. Harold Hinman was chosen president-elect of the National Malaria Society at its twenty-ninth annual meeting in Miami, Fla., Nov. 4 to 7, and Dr. Mark D. Hollis was installed as president.——Dr. Willard O. Thompson, Chicago, was chosen president-elect of the Mississippi Valley Medical Society during its eleventh annual meeting recently, and Dr. Walter A. Sternberg, Mount Pleasant, Iowa, was inducted into the presidency.——The newly elected officers of the Central Association of Obstetricians and Gynecologists are as follows: Drs. Earl C. Sage, Omaha, president; William F. Mengert, Dallas, Texas, president-elect; George A. Kamperman, Detroit, vice president; John I. Brewer, Chicago, secretary-treasurer, and Harold L. Gainey, Kansas City, Mo., assistant secretary-treasurer.——At the fifty-eighth annual session of the Southern Surgical Association in Hot Springs, Va., Dec. 10-12, 1946 Dr. Frank S. Johns, Johnston-Willis Hospital, Richmond, Va., was elected president. Vice presidents named were Dr. Charles Reid Edwards, Baltimore, and Dr. Frank C. Wilson, Birmingham, Ala.——Dr. Irvin Abell, clinical professor of surgery, University of Louisville School of Medicine for over forty years, was inaugurated president of the American College of Surgeons at the recent meeting in Cleveland Dr Abell is a past president of the American Medical Association, the Southern Medical Association and the Southern Surgical Association

Annual Meeting of American Academy of Orthopaedic Surgeons—The fourteenth annual meeting of the American Academy of Orthopaedic Surgeons will be held in the Palmer House, Chicago, January 25-30 Dr Myron O Henry Minneapolis, secretary of the academy, estimates that more than 800 bone and joint surgeons from the United States, Canada and Mexico will attend Preceding the formal meeting, which opens Monday, January 27, there will be a series of lectures covering various phases of orthopedic surgery Speaking at the instructional course dinner at 7 p m January 25 will be Dr James E M Thompson, Lincoln Neb president of the academy, whose subject will be 'Orthopedic Surgery Behind the Iron Curtain" and Sir Reginald Watson Jones, professor of orthopedic surgery at the University of London and orthopedic surgeon to the King of England who will discuss Personal Experiences as Consultant for the Royal Army Air Force ' Dr Thompson visited medical colleges and medical centers in Europe last summer The academy s annual historical dinner will be held Tuesday evening, January 28 and the annual dinner and dance will take place Wednesday evening The committee in charge of the Chicago meeting is headed by Drs Edwin W Ryerson, Chicago, honorary chairman, who served as the academy s first president and John R Norcross, Chicago, general chairman

Recommendations of Public Health Cancer Association—The Public Health Cancer Association of America comprising numbers of both voluntary and official cancer control agencies, at a recent special meeting in Cleveland adopted the following resolutions and recommendations

1 That a national cancer control advisory committee be formed to help achieve integration and cooperation among the national organizations now engaged in cancer control

2 That similar committees be organized in each state and community having an organized cancer program

3 That a representative of the U S Public Health Service cancer control division and an individual representing state health department divisions of cancer control be included in the national committees of the American Cancer Society

4 *That an official cancer control program be organized in each state* department of health

5 That an official state agency be established in each state for confidential cancer morbidity reporting case registration and follow up

6 That schools of public health make increased provision for the training of cancer control administration officers

7 That the importance of thorough and complete periodic health examinations of apparently well persons be emphasized

8 That more funds be made available to meet the needs for care of advanced cancer patients

9 *That the role of voluntary agencies in supplementing official cancer* control programs in stimulating and supporting the development of complete and continuing control programs be emphasized

The association elected as president Dr Morton L Levin, Albany, director of the New York State Health Department's division of cancer control, to succeed Dr Herbert L Lombard Boston, Massachusetts Department of Health

Gift to Establish a Chorionepithelioma Registry—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons has accepted a generous gift from Dr Albert W Holman Portland Ore for a registry of material dealing with the hydatidiform mole and chorionepithelioma It is to be a memorial to the late Dr Albert Mathieu joint author with Dr Holman of papers dealing with this subject A committee to carry out the purpose of the registry has been appointed Drs Emil Novak, Baltimore, Albert W Holman, Willard R Cooke, Galveston Texas, Robert A Ross, Durham N C, James R Miller, Hartford, Conn, and Herbert E Schmitz, Chicago Since there is no crystallization of opinion as to histologic criteria of malignancy in lesions of this group and no one laboratory can expect to accumulate a sufficient number of these relatively rare lesions to permit satisfactory studies on this point it is hoped that clinics and laboratories throughout the country will cooperate by sending in material of this sort Thus the registry will be able to accumulate a large storehouse of material which can be authoritatively studied and for which there will be adequate clinical data as well as follow up studies Communications and material may be directed to the chairman of the committee, Dr Emil Novak 28 East Preston Street, Baltimore, or to Johns Hopkins Hospital Laboratory of Gynecological Pathology, Baltimore Simple clinical forms to facilitate supplying adequate clinical data will be mailed to those sending in material

Official Number of Deaths—Figures just released by the U S Public Health Service place the total number of deaths reported in continental United States exclusive of deaths in the armed forces overseas, in 1945 at 1,401,719 This was a smaller number than was reported in the two preceding war years The number due to tuberculosis was 3 3 per cent less than in 1944 and fewer than in any previous year Deaths from pneumonia and influenza were 16 4 per cent fewer than in 1944 and 8 2 per cent less than the previous minimum in 1942 Heart diseases accounted for 30 3 per cent of the reported deaths as compared with 29 6 in 1944 Cancer claimed 12 7 per cent of the total as compared with 12 1 per cent in 1944 All accidental causes accounted for 95,918 deaths, which number includes 28 076 deaths due to motor vehicle accidents The *same ten causes which led the list in 1945* are those which headed the list in the two prewar years, and, with the exception of motor vehicle accidents, they rank in the same order The ten leading causes of death in the United States in 1945 were

Heart diseases	424,328
Cancer and other malignant tumors	177 464
Intracranial lesions of vascular origin	129,144
Nephritis	88 078
Pneumonia and influenza	68 386
Accidents, excluding motor vehicle accidents	67,842
Tuberculosis	52,916
Diabetes mellitus	35,160
Premature birth	31,614
Motor vehicle accidents	28 076

New Research Institute for Tropical Medicine in Liberia.—The president of Liberia, West Africa William V S Tubman, announces that an international research institute for tropical medicine will be built in that country during 1947. The research center, which will be located near Roberts Field, an international airport, is sponsored by the American Foundation for Tropical Medicine, Inc, New York A $250,000 grant to the Liberian government for buildings and equipment was made in August 1946 by Harvey S Firestone Jr The American Foundation for Tropical Medicine a nonprofit corporation which carries on scientific enterprises in support of tropical medicine, has assured the maintenance and operation of the Liberia Institute at an estimated primary cost of $100 000 a year The Liberian government has contributed a building site of about 100 acres adjacent to Roberts Field and fronting the beautiful Farmington River, also a supplementary 600 acre site for operating a livestock range and for veterinary research and training The advantages in locating a research institute in Liberia are those incident to a highly staple tropical climate and opportunities for research in parasitology, pathology and nutrition general surgery, virus diseases including poliomyelitis spirochetal diseases and filariae, malaria and other tropical diseases, many of which menace all nations All findings of the institute are to be disseminated to all interested medical institutions and scientists An active research program is expected to be under way by 1948 Exchange fellowship agreements have already been made with seven schools of tropical medicine in the British Isles and Europe, also with the Louis Pasteur Institute American medical schools represented on the scientific advisory committee for the Liberian Institute include Harvard, Tulane, Johns Hopkins, Stanford California, Bowman Gray Southern California, Michigan Chicago New York University, Duke, Long Island Medical School and the medical schools of Howard and Meharry universities Other institutions serving in an advisory capacity include the Eli Lilly Research Laboratories, the Squibb Institute for Medical Research the Army Medical College, the Winthrop Chemical Company, the Gorgas Memorial Institute and the United Fruit Company

CORRECTION

Carotid Sinus Syndrome—*In the editorial by this name* in THE JOURNAL Sept 7 1946, in line five, second paragraph, second column on page 24 "A solution of epinephrine sulfate" should read 'A solution of atropine sulfate

Marriages

AUBREY OTIS HAMPTON, Boston, to Mrs Astrid Irene Young at Chevy Chase Md, September 16

WALTER J ROBERTS to Mrs Alice Eleanor Stewart, both of Rochester, N H, in September

WILLIAM T O CONNELL, Boston, to Miss Dorothy M. Hogue of New Castle, Pa, in September

GEORGE R LOVFALL to Miss Olive Louise Reppard, both of San Diego, Calif, September 22

CHARLES D SCHAEFFER to Miss Sallie Ann Koch, both of Allentown, Pa, September 14

Deaths

Reuben Bennett Anderson Jr. ⊕ Fort Worth, Texas, for almost twenty years assistant secretary of the State Medical Association of Texas and assistant editor of the *Texas State Journal of Medicine;* died January 2, aged 52, of coronary occlusion. Dr. Anderson was born in Seguin, Texas, Dec. 14, 1894. He attended the public schools of Sherman, Texas, and graduated from Austin College in Sherman in 1914. He graduated from the University of Texas School of Medicine, Galveston, in 1918, served an internship at the John Sealy Hospital and later did postgraduate work in eye, ear, nose and throat in New Orleans. Dr. Anderson then was commissioned a lieutenant in the medical corps of the navy, serving for about two and one-half years, first in New Orleans, then with the Transport Service and then in Santo Domingo. He returned to Texas in 1921 to begin the practice of medicine at San Marcos and moved to Thorndale in 1923, where he served as a member of the school board and where he practiced until 1927, when he joined the staff of the state medical association in the assistant secretary-editor, positions, which he held at the time of his death. He was recently made librarian of the association. Dr. Anderson had served as alternate delegate from Texas to the American Medical Association since 1927 and on three occasions, the last in December 1946, served as delegate. He was at one time a member of the Fort Worth Eye, Ear, Nose and Throat Society, a past president and member of the board of directors of the Fort Worth Anglers Club, and a member of Tarrant County Wildlife Association and of the Lake Worth-Eagle Lake advisory board to the Texas Game, Fish and Oyster Commission. Dr. Anderson was vice chairman for Texas of Procurement and Assignment for Physicians in World War II and chairman of the Committee on Public Relations of the State Medical Association of Texas for about a year and a half up to May 1946.

Alexander James Barclay, Newburgh, N. Y.; born in Ardonia, N. Y., Feb. 13, 1896; Cornell University Medical College, New York, 1928; member of the American Medical Association; interned at the New York Post-Graduate Medical School and Hospital in New York and the Psychiatric Institute in Morristown, N. J.; served on the staffs of the Cornwall (N. Y.) Hospital and the St. Luke's Hospital; fellow of the American College of Surgeons; served during World War I; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve in April 1942; spent twenty-eight months as chief surgeon aboard a transport, after having taken part in the landing in North Africa; promoted to commander; demobilized in January 1946; accidentally shot and killed near Limerick, Maine, Oct. 31, 1946, aged 50, when a member of his hunting party fired at what he thought was a deer.

Andrew Jay Timberman, Columbus, Ohio; born in Hamilton, Ohio, May 10, 1864; Miami Medical College, Cincinnati, 1894; member of the American Medical Association and the American Academy of Ophthalmology and Oto-Laryngology; past president of the Columbus Academy of Medicine; fellow of the American College of Surgeons; served on the faculties of Ohio Medical University, Starling Ohio Medical College and Ohio State University College of Medicine; formerly member of the city board of education; specialist certified by the American Board of Ophthalmology; oculist for the medical advisory board, Columbus District, U. S. Army, from 1917 to 1919; on the staffs of the Soldiers' and Sailors' Orphans Home Hospital in Xenia, the University and St. Francis hospitals; trustee, Otterbein College; died Oct. 15, 1946, aged 82.

Charles Darwin Enfield ⊕ Louisville, Ky.; born in Jefferson, Iowa, July 7, 1887; Rush Medical College, Chicago, 1909; interned at Kansas City General Hospital in Kansas City, Mo.; specialist certified by the American Board of Radiology; a member of the medical advisory board of Selective Service, the Association for the Study of Neoplastic diseases, Southern Medical Association, American Roentgen Ray Society and the American College of Radiology; radiologist at St. Anthony's Hospital, Norton Cancer Clinic and Norton Memorial Infirmary; died Nov. 14, 1946, aged 59.

George Frederick Beachler, Cleveland; University of Wooster Medical Department, Cleveland, 1895; died in the University Hospital Nov. 27, 1946, aged 78, of bronchopneumonia.

Charles Bernhardt Behrens, Los Angeles; College of Medical Evangelists, Los Angeles, 1935; member of the American Medical Association; diplomate of the National Board of Medical Examiners; accidentally shot and killed Oct. 19, 1946, aged 46.

Rudolph Boenke ⊕ Long Island City, N. Y.; University and Bellevue Hospital Medical College, New York, 1911; member of the American Academy of Dermatology and Syphilology; died Oct. 27, 1946, aged 71, of coronary embolism.

Oscar Winfred Carper, Front Royal, Va.; Medical College of Virginia, Richmond, 1931; interned at the Hazleton State Hospital in Hazleton, Pa.; past president of the Medical Society of Northern Virginia; secretary and past president of the staff of Front Royal Hospital; member of the board of directors of Citizens National Bank of Front Royal; past president of the Front Royal Rotary Club; died in the University of Virginia Hospital, Charlottesville, Oct. 26, 1946, aged 43, of hypernephroma.

John George Carr, Pittsburgh; University of Pittsburgh School of Medicine, 1942; interned at the Mercy Hospital; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve in April 1943; promoted to lieutenant; released from active duty in September 1946; served with field hospitals during most of the Pacific war; had seen much action, including the invasions at Saipan and Tarawa; died in Homestead, Pa., Oct. 27, 1946, aged 29, of injuries received in an automobile accident.

Frank Riley Castleman, Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1921; for many years professor of physical education at the Ohio State University; died Oct. 9, 1946, aged 69, of cerebral hemorrhage.

William Chapman Chilton, Jr., Appomattox, Va.; Medical College of Virginia, Richmond, 1943; interned at the Baptist Memorial Hospital in Memphis; began active duty as a first lieutenant in the medical corps, Army of the United States, in December 1943; promoted to captain in January 1945; relieved from active duty on Aug. 8, 1946; died in the Medical College of Virginia Hospital, Richmond, Sept. 20, 1946, aged 30.

Nathan W. Church, Ulysses, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the American Medical Association; served on the board of education, as school physician in Ulysses and as president of the Ulysses Grange National Bank; for many years physician for the New York Central Railroad; died Oct. 16, 1946, aged 77, of cardiac decompensation.

James R. Connell, Wartrace, Tenn.; University of Tennessee Medical Department, Nashville, 1893; served as president of the Middle Tennessee Medical Association; died in October at St. Thomas Hospital in Nashville, aged 80.

Robert Elisha Downing, Lexington, Ky.; Emory University School of Medicine, Atlanta, Ga., 1930; specialist certified by the American Board of Radiology; member of the American Medical Association, Radiological Society of North America and the American College of Radiology; on the staff of the Good Samaritan Hospital of Lexington; served during World War II; died in Brewton, Ala., Oct. 5, 1946, aged 41, of coronary occlusion.

Melvin Dresbach, Philadelphia; Ohio Medical University, Columbus, 1903; served on the faculties of the Cornell University in Ithaca, N. Y., Albany (N. Y.) Medical College, Ohio State University and Starling-Ohio Medical College in Columbus; member of the American Physiological Society and of the Society for Experimental Biology and Medicine; died Oct. 15, 1946, aged 72, of coronary occlusion.

Frederick York Durrance ⊕ Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1925; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc., and the American College of Radiology; associate professor of radiology at the Baylor University College of Medicine; chief of the radiologic department of the Hermann Hospital; died Oct. 29, 1946, aged 53, of coronary thrombosis.

Henry Theodore Foshager ⊕ Clara City, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; died in Stoneham township Oct. 19, 1946, aged 65, of injuries received in an automobile accident.

John Paulett Haller, Salem, Va.; Medical College of Virginia, Richmond, 1882; member of the American Medical Association; died Oct. 24, 1946, aged 85, of Parkinson's disease.

Byrt Boone Hutton, Harrisburg, Ill.; Barnes Medical College, St. Louis, 1908; member of the American Medical Association; at one time president of the Saline County Medical Society; on the staff of the Lightner Hospital; died in the Lutheran Hospital, St. Louis, Oct. 22, 1946, aged 62, of atelectasis of the right lower lobe, diverticulum of the sigmoid and cirrhosis of the liver.

John Paul Jones, Mitchell, S. D.; Northwestern University Medical School, Chicago, 1939; member of the American Medical Association; began active duty as a captain in the medical corps, Army of the United States, in Feb. 8, 1941; spent three years in the European theater; discharged as a major Sept. 9, 1945; resumed practice in November 1945; on the staff of St. Joseph Hospital and Methodist State Hospital, where he died Oct. 30, 1946, aged 36, of pneumonia.

John Arthur Kneller, Attica, N. Y.; University of Buffalo School of Medicine, 1912; member of the American Medical Association; served as county coroner and mayor; health officer of Bennington township; died in the Buffalo General Hospital Oct. 20, 1946, aged 57, of nephrosclerosis and hypertension.

George W. McFatrich, Chicago; Bennett Medical College, Chicago, 1891; interned at the Cook County Hospital, where he was ophthalmologist; died in the Passavant Memorial Hospital Nov. 10, 1946, aged 76, of intracranial hemorrhage.

Marion Blanche Neil, Forest City, Iowa; Northwestern University Woman's Medical School, Chicago, 1901; formerly in charge of social welfare work in Winnebago County; died Oct. 9, 1946, aged 68, of coronary artery disease.

Ivo Amazon Nelson, Tulsa, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1925; specialist certified by the American Board of Pathology, Inc.; member of the American Society of Clinical Pathologists; served as pathologist on the staff of St. John's Hospital; associated with the Nelson Pathological Laboratories, which he founded; died Oct. 21, 1946, aged 52, of myocardial failure.

Otto Charles Pinc ⊕ Chicago; Rush Medical College, Chicago, 1924; interned at the Kings County Hospital in Brooklyn; resident physician at the Cook County Infirmary in Oak Forest, Ill.; on the staff of the Bethany Sanitarium and Hospital; captain, medical reserve corps, U. S. Army, not on active duty; died in the Albert Merritt Billings Hospital Nov. 9, 1946, aged 46, of hypertension and cardiovascular disease.

David Giltner Pryor, Jeffersonville, Ind.; University of Louisville (Ky.) School of Medicine, 1931; member of the American Medical Association; president of the staff of the Clark County Memorial Hospital; served as president of the Rotary Club; died Oct. 27, 1946, aged 43, of coronary occlusion.

George W. Sargent, Seneca Castle, N. Y.; Syracuse University College of Medicine, 1879; member of the American Medical Association; served as health officer; died Oct. 1, 1946, aged 93, of arteriosclerosis.

Anton Henry Schaefer, Berkeley, Calif.; Stanford University School of Medicine, San Francisco, 1941; member of the American Medical Association; interned at the Alameda County Hospital in Oakland; served a residency at Ernest V. Cowell Memorial Hospital; died in Alta Bates Hospital Sept. 29, 1946, aged 41, of lymphosarcoma.

Cortlandt Whitehead Schepeler ⊕ Brooklyn, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1915; served during World War I; on the staffs of the Mercy Hospital and the Foote Memorial Hospital, where he died Oct. 27, 1946, aged 55, of cerebral hemorrhage.

Joseph Otto Segura, Jackson, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1910; member of the American Medical Association; vice president and medical director of the Lamar Life Insurance Company; served in England during World War I; died in a hospital at Abbeville, La., Oct. 26, 1946, aged 59, of coronary occlusion.

Jeannette M. Shefferd ⊕ Fall River, Mass.; John A. Creighton Medical College, Omaha, 1912; specialist certified by the American Board of Otolaryngology; member of the New England Otological and Laryngological Society; on the staff of the Union Hospital, where she died Oct. 23, 1946, aged 67, of carcinoma of the colon.

Joseph Scott Snider ⊕ Kansas City, Mo.; University Medical College of Kansas City, Mo., 1900; served during World War I; an Affiliate Fellow of the American Medical Association; on the staff of St. Mary's Hospital, where he died Oct. 29, 1946, aged 70, of carcinoma of the right lung.

Charles C. Snowden, Davenport, Neb.; Jefferson Medical College of Philadelphia, 1882; member of the American Medical Association; died in Lincoln Oct. 25, 1946, aged 91, of pneumonia.

David Henry Stern, Hammond, Ind.; University of Illinois College of Medicine, Chicago, 1937; member of the American Medical Association; served during World War II; on the staff of St. Margaret Hospital, where he died June 13, 1946, aged 38, of coronary thrombosis.

Rae Latham Strong ⊕ Bloomingdale, N. Y.; University of Buffalo School of Medicine, 1899; for many years health officer; on the staffs of Champlain Valley and Physicians hospitals in Plattsburg and General Hospital in Saranac Lake, where he died Oct. 18, 1946, aged 70, of arteriosclerosis.

John William Thomson ⊕ Garrett, Ind.; Rush Medical College, Chicago, 1909; for many years president of the school board; past president of the De Kalb County Medical Society and of the Northeastern Indiana Academy of Medicine; served during World War I; member of the American Association of Railway Surgeons; surgeon for the Baltimore & Ohio Railroad; on the staffs of the Sacred Heart Hospital in Garrett and the McCray Memorial Hospital in Kendallville; died Oct. 17, 1946, aged 60, of uremia.

DIED WHILE IN MILITARY SERVICE

Hubert Benjamin Bradburn ⊕ Lincoln, Ill.; Washington University School of Medicine, St. Louis, 1927; fellow of the American College of Surgeons; formerly city physician; served an internship and as resident physician at the Vanderbilt University Hospital in Nashville, Tenn.; began active duty as a captain in the medical corps, Army of the United States, on July 17, 1942; promoted to major; died in the Walter Reed General Hospital, Washington, D. C., Sept. 4, 1946, aged 45, of mesenteric thrombosis.

Harold Edward Hanley, Richmond Hill, N. Y.; New York University College of Medicine, New York, 1943; interned at the Bellevue Hospital in New York; began active duty as a first lieutenant in the medical corps, Army of the United States, on Oct. 15, 1944; following his assignment in Hawaii was stationed in Japan, where he was attached to the 98th Division and where he died May 23, 1946, aged 27, of a skull fracture received in an accident.

Isaac Newton LaVictoire, Pigeon, Mich.; Yale University School of Medicine, New Haven, Conn., 1928; member of the American Medical Association; interned at the Conemaugh Valley Memorial Hospital in Johnstown, Pa.; served a residency at the Kalamazoo State Hospital in Kalamazoo; at one time affiliated with the State Prison of Southern Michigan in Jackson and the Michigan Reformatory in Ionia; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve in 1933; began active duty in February 1941; sent to the Philippines and was stationed at Cavite naval base near Manila when the Japanese struck; fought with the navy until the fall of Cavite; moved to Manila, where he fell prisoner of the Japs; imprisoned for three years at the Cabanatuan prison camp; shortly after the invasion of the Philippines by American forces the prison camp was liberated by American rangers and he was one of the 483 American personnel liberated; promoted through the grades to captain; died March 2, 1946, aged 43, of coronary thrombosis and general debility incurred while a prisoner of war of the Japanese.

Maurice James McElligott, Lynn, Mass.; Rush Medical College, Chicago, 1937; member of the American Medical Association and the Illinois State Medical Society; interned at the Boston City Hospital in Boston, where he served a residency; served a residency at the Westfield State Sanatorium in Westfield; captain in the medical corps, Army of the United States; died in Denver April 25, 1945, aged 42, of coronary occlusion.

Frank W. Wilson ⊕ Colonel, M. C., U. S. Army, Swannanoa, N. C.; University of Maryland School of Medicine, Baltimore, 1914; Army Medical School in 1916; Medical Field Service School Advanced Course, Carlisle Barracks, in 1934; born in Greenville, N. C., April 29, 1888; fellow of the American College of Physicians; member of the Medical Association of Georgia; specialist certified by the American Board of Internal Medicine; given a reserve commission in the medical service of the army in August 1915 and appointed to the medical corps in 1916; served on the Mexican border, followed by oversea duty in World War I; had three tours of duty at Walter Reed Hospital in Washington and a long period of service at Fort Benning, Ga.; placed in charge of the Station Hospital at Camp Shelby, Miss., in 1940; assigned to command the Moore General Hospital in 1942 when it was established and where he died April 20, 1946, aged 58, of coronary thrombosis.

Body Temperature as Guide to Determining the Time of Death

Dr. C. Keith Simpson, medicolegal pathologist, who has done remarkable work in the identification of the mutilated and buried remains of a murdered woman, recently gave attention to deciding how long a person has been dead (*Science Progress*, October 1946, p. 713). He holds that the most reliable guide is the steady fall of temperature which takes place for twenty-four hours after death. Under average conditions he finds that about 2.5 degrees F. is lost hourly for the first six hours and from 1.5 to 2 degrees F. hourly for the next six hours. Calculations based on these figures may be upset by extremes of temperature, the amount of clothing worn, ventilation and environment. Thus a body in a river will reach the temperature of the surrounding atmosphere much more quickly than one on dry land. If parasites such as fleas and lice are present, the entomologist may help by finding out whether they are still alive and, if so, how long it takes to revive them. Adipocere may hinder rather than help, for hydrogenation of body fat is variable. With warmth it may take place in three or four weeks or it may be delayed beyond the four or five months which is the average in England. The onset of rigor mortis or of postmortem lividity is of little use in deciding the time of death. Simpson concludes that in estimating the time of death the most reliance is to be placed on the body temperature. It is never too late, he says, to measure this. Though the body is cold it may still register a few degrees above its surroundings. As an example he cites a murder in which the body temperature was still 7 degrees F. above the temperature of the air, although it had lain eighteen hours in the snow. This made it possible to fix the time of death within an hour.

Government Plan for Taking Over the Voluntary Hospitals

The voluntary hospitals are so called because they were founded and until recent years were entirely supported by the voluntary subscriptions of the charitable. They comprise the great hospitals which are medical schools. Following closely the passage of the National Health Service Act the Ministry of Health has produced an elaborate plan for taking over all the hospitals, though it does not propose to interfere with the autonomy of the medical schools. For purposes of administration the whole country has been mapped into areas, each with a university medical center as a focal point—Manchester, Leeds, Birmingham, Sheffield, Liverpool, Bristol, Newcastle, Cardiff, Oxford and Cambridge. London has four areas, northwest, northeast, southeast and southwest, each extending into the adjacent country. For all these areas regional hospital boards are to be appointed to administer the hospital and specialist services. For the benefit of any observations which may be made the Ministry of Health has issued a circular to the local bodies and organizations concerned. The size and extent of the areas will be determined by their purpose, which is to provide an area adapted rather for the planning, coordination and provision of hospital and specialist services rather than for the control and management of hospitals. The latter task will be the function of hospital management committees. It follows that the areas must be comparatively large in population. The boundaries of the areas will not prevent patients from freely passing from one area to another. Whenever possible the boundaries of the areas should coincide with those of local health authorities, but other important factors, such as association of services with medical schools or grouping of related hospitals with the same regional board, make it necessary to cross such boundaries.

Anglo-French Medical Cooperation in West Africa

At an Anglo-French medical conference held at Accra, Gold Coast, West Africa, a system of cooperation in many aspects of public health and medical work in the West African territories was agreed on. Pathologic laboratories in the area will be used according to geographic convenience rather than international boundaries. It is hoped to organize during the coming year experiments in joint campaigns in frontier areas where the ravages of sleeping sickness, smallpox or yellow fever occur on both sides of the border. The conference had its origin in arrangements for closer Anglo-French cooperation in colonial matters, but experts who attended from the Belgian Congo and from Portugese Guinea and Liberia expressed agreement with the principles underlying the recommendations and their desire to develop similar cooperation.

Discussion on Experimental Diabetes

At a recent meeting of the Sociedad Argentina de Biologia, Drs. B. A. Houssay, R. F. Brignone, A. F. Cardeza and J. G. Sara, of Buenos Aires, reported experiments on dogs which had transient diabetes after the injection of alloxan and which developed permanent diabetes after prolonged treatment with thyroid. This form of metathyroid diabetes from alloxan is a pancreatic diabetes due to lesion on the beta cells of the islands of Langerhans (degranulation and strong diminution in number). The administration of thyroid does not produce diabetes unless the resistance of the pancreas has been diminished and the condition of the pancreatic beta cells has been changed.

Dr. C. Martinez discussed the influence of hyperthyroidism on alloxan and pancreatic diabetes in white rats: (*a*) thyroid administered for twenty consecutive days increases sensibility to alloxan, whereas if it is given for sixty consecutive days it gives the animals a supernormal resistance; (*b*) thyroid treatment of rats after ample pancreatectomy (removal of 95 per cent of the pancreas) causes the appearance of diabetes in the first two weeks of treatment. After this period of time diabetes gradually disappears even if the administration of thyroid is continued; (*c*) thyroid treatment of rats with ample pancreatectomy in the early period of diabetes causes total disappearance of diabetes, and (*d*) the favorable effect of thyroid seems to be due to stimulation of the pancreatic islands and to hyperplasia.

Drs. S. Gitter and A. F. Cardeza discussed the diabetogenic effect of substances with chemical resemblance to alloxan, namely, alloxantin, methylalloxan and dialuric, barbituric and violuric acids. Two different histologic types from the diabetogenic effect are observed in the islands of Langerhans: (*a*) coagulation necrosis of the beta cells (from alloxan, alloxantin and dialuric acid) and (*b*) degeneration of the beta cells without coagulation necrosis (from either barbituric or violuric acids).

Drs. B. A. Houssay and P. Mazzocco discussed the effects of either diethylstilbestrol or alloxan on glycemia and glycogen in rats. Administration of sugar after fifteen hours of fasting to rats either normal or with alloxan diabetes, causes a more acute hyperglycemia and a smaller amount of glycogen in the liver and muscles of the latter than in those of the former. Administration of sugar after fifteen hours of fasting to rats, either normal or with alloxan diabetes which had diethylstilbestrol treatment, caused an increase of glycemia, moderate in normal rats and acute in rats with alloxan diabetes. The increase of the hepatic and muscular glycogen was moderate in normal rats and acute in rats with alloxan diabetes.

Dr. Carlos Martinez discussed age in relation to diabetes in rats. Subtotal pancreatectomy (95 per cent) in male rats aged 10 days caused noncomplicated benign diabetes in a small percentage of the animals. In animals aged 547 days, or more, it caused in almost all the early appearance of diabetes of acute course and complicated by acute infections and the early appearance of cataracts. Progressive loss of body weight was acute and mortality high (75 per cent) in this group. In rats aged 60 to 70 days, diabetes occurred in all the animals in the lot. The mortality was 25 per cent in this group. The results of the experiments show that in young animals the pancreas has a better opportunity for regeneration after pancreatectomy. Because of the size of the pancreas at this age, it is probable that the removed portion of the structure is smaller than one believes during performance of experimental pancreatectomy. The number of island cells is greater in young rats than in adult rats.

Drs. E. Moisset de Espanés, B. Weksler and E. Ortega, of Cordoba, reported results of experiments of studies on the toxicity of alpha-fagarine. The following results were encountered: One hundred male rats (Wistar strain) had intraperitoneal injections of alpha-fagarine solutions. The values of the lethal dose (50 per cent) varied from 90 to 117.1 mg. for each kilogram of body weight, in accordance with different methods used for its determination. The greatest tolerated dose is 74 mg. for each kilogram of body weight. The lethal dose (100 per cent) is 196 mg. for each kilogram of body weight. The lethal dose (50 per cent) for dibencyl-methyl-amine in rats, by intraperitoneal route, is 656 mg. for each kilogram of body weight. Consequently alpha-fagarine is 7.17 ± 1.44 times more toxic than dibencyl-methyl-amine. Determinations of the toxicity of alpha-fagarine were also carried out on rabbits. Ten lots of rabbits each had intravenous injections of alpha-fagarine solution in doses which varied from 2 to 4 per cent. The average lethal dose (LD 50) varied between 14 and 20 mg. for each kilogram of body weight, according to the different methods used for the determination. The greater tolerated dose (LD 0) was about 4 mg. for each kilogram of body weight and the 100 per cent lethal dose (LD 100) was 30 mg. for each kilogram of body weight. The response to the effect of alpha-fagarine was more uniform in rats than in rabbits.

Retirement of University Professors

The statute of the National University of Buenos Aires makes 65 the retirement age of professors, unless the person wishes to retire five years earlier. Through a decree, this regulation was modified for all the universities in the country. Professors retire in accordance with the law for civilians working in public administration, by which employees retire at age 55 and after thirty years of work. The new regulation has been applied to the University of Buenos Aires. The professors immediately eligible for retirement according to the new regulation included Drs. B. A. Houssay, Alejandro Ceballos, José María Jorge and Juan A. Gabastou, who were declared dismissed through retirement. Drs. Eduardo Braun Menéndez and R. Foglia of the Faculty of Medical Sciences of Buenos Aires, Oscar Oria and E. Moisset de Espanés of the Faculty of Cordoba and J. T. Lewis of the Faculty of Rosario resigned because of the dismissal of Dr. Houssay.

Dr. Houssay, who is 59 years old, received this news just as he was leaving Argentina to attend special ceremonies in Canada and the United States in celebration of the 25th anniversary of the discovery of insulin. The University of Toronto gave Dr. Houssay the 1945 "Charles Micle" prize for his work in medicine. He delivered important lectures at the University of Toronto, the National Academy of Sciences in Washington, the American Philosophical Society of Philadelphia and other universities. He was recently appointed Professor honoris causa of the Universities of Brazil, Lyon (France) and Montreal.

JAPAN

(From a Special Correspondent)

TOKYO, Nov. 1, 1946.

Reform of Medical Education in Japan

An important innovation in Japanese medicine will be the establishment of a modern internship system throughout the country. Under the guidance of Major S. E. Molten, chief laboratory consultant for the public health and welfare section of general headquarters, an archaic system wherein postgraduate students often remained behind in their university hospitals to work for higher degrees will be abandoned. In prewar Japan these students seldom had an opportunity to assume actual responsibility for patients. An average clinic in these university hospitals could have two interns assigned to each patient. This concentration of young doctors in a few medical centers will cease to be a general characteristic of Japanese medicine as a general reform program of the Education and Health ministries gets under way. It is intended that the number of beds in the metropolitan hospitals which are available for internship assignment will be carefully limited. Present plans, calling for the enforcement of a quota of 10 to 25 patients to the care of one intern, will cause a migration of young interns to smaller cities and prefectural health centers in Japan. It is hoped by allied officials that such a move will tend to liberate Japanese medicine and medical education from their tendency toward citadelism and the throttling effect of academically isolated cliques among members of the profession. Assignment of interns from more than one school to a particular hospital is intended to produce an overlapping of school influences. This should result in an active exchange of specialized knowledge and constructive criticism of personal technics. Example and competition have always proved a major factor in elevation of medical standards.

It would not be incorrect to epitomize this sweeping reform in the intersystem of Japan as the assumption of much greater responsibility on the part of young Nipponese doctors., As part of the general medical reform they will now work as doctors and not students during the period of internship. Older and more experienced doctors will be expected to engender in their disciples the true meaning of responsibility and trust. American public health officers hope that this change will also benefit the experienced doctors and surgeons, for in their meeting and working with young interns who are full of enthusiasm and theory they will be exposed to what is new in turn for teaching what is old but yet true. Major Molton has signified this plan as "the old idea of apprenticeship brought up to date for the benefit of medicine in Japan."

Living Quarters for Interns

Still unsolved by most hospitals in occupied Japan is the problem of adequate living facilities for interns. Since few of the hospitals in this country are operated on a nonprofit basis it is difficult to discuss with them the value of an internship in terms of financial outlay. No immediate remedy is expected by occupation officials. It is hoped that hospitals will come to realize the true value of good interns. The result of this change in attitude should be a healthy competition for young doctors together with concurrent improvement in living quarters and intern pay. Some progress in this matter can already be noted where the "medical center" idea is taking hold in a few large cities. Another change in the curriculum of study-practice followed by Japanese interns since the war, and one employed nowhere else in the world (to my knowledge) is the provision for one month of work by each intern in an approved health center at the prefectural level. Taking the intern out of the Japanese metropolis and sending him to such a local health unit means that he is doing actual field work in the public health sphere of activities. This plan should result in many more doctors who are conscious of problems of a public health nature.

TREATMENT OF VARICOSE VEINS

To the Editor:—Dr. Gerald H. Pratt's article on the Treatment of Varicose Veins, in THE JOURNAL, Nov. 23, 1946, suggesting the use of interval suspension of the distal stem of the resected "blowouts" in varicose vein surgery, proves further to me that the work of Dr. R. Stanton Sherman of San Francisco is the closest approach to complete success. If the workers in this field will refer back to his articles, starting with *California and Western Medicine* in September 1942, through the later ones in the *Annals of Surgery* in November 1944, they will find the anatomic basis for his extensive operative procedure of bilateral high saphenous vein ligation, perforator interruption and stripping, with short saphenous ligation and perforator interruption, as well, in many cases where it is indicated.

The anatomic pattern of the venous system of the lower extremity is easily visualized in cross section roughly as a wagon wheel. The hub represents the deep venous circulation, whereas the rim represents the superficial or saphenous system. The spokes represent the leaking incompetent perforators. Through this system the venous blood circulates, and in cases of varicosis with leaking valves in the saphenous and communicating or perforator veins the greater pressured deep venous blood runs backward to fill the outer system at the many levels of incompetent perforators. The latter, mainly, are the saphenofemoral junction, mid-Hunter canal area and the geniculate and short saphenous veins about the knee and various sites in the leg. The latter have been described in great part by Dr. Linton.

To eliminate "blowouts" per se is not eliminating leaking perforators, as the location of the former does not necessarily signify the location of the entrance of the perforators into the deep system except in the leg at certain sites. The perforators of the thigh and knee run obliquely upward and inward, and their entrance into the deep system is therefore higher than the location of a "blowout," and they must be ligated close to the deep femoral vein, not in the superficial tissues. A "blowout" may also not be at the site of any leaking perforator.

My own operative experience coincides with that of Dr. Pratt in that approximately one fourth to one third of all my cases are ones previously treated with high saphenous vein ligation alone or with interval saphenous vein or "blowout" ligation in addition. There is a great deal more accurate knowledge necessary in regard to the sites of the perforators of the thigh and leg. Sherman has added greatly to our knowledge of these, particularly of the thigh and knee regions, by his contributions. The sites of leaking perforators of the anterior, mesial and posterior leg are also quite well established. The mesial lower leg perforators, 18-20 cm. above the sole of the mesial border of the foot, mentioned by Sherman, are more or less constant offenders. Their presence cannot always be definitely determined before exploration. When the perforator locations are definitely known, we shall then achieve greater success in their elimination and we shall not have to depend on tests for their presence. Leakage from them is present in practically all cases. All tests, at best, are only partially helpful.

Referring back to the similarity of the venous system to a wagon wheel, real success will come only when all spokes of the wheel are interrupted at all levels at which they occur, as far back toward the hub as we can possibly go.

ROBERT A. OSTROFF, M.D., Beverly Hills, Calif.

ENURESIS

To the Editor:—In the November 30 issue of THE JOURNAL a communication from Dr. Edwin E. Ziegler, appearing under Correspondence, recommends the "start and stop" method of treatment for enuresis. I was impressed with this regimen while working in the Behaviour Clinic of the late Dr. Ira S. Wile in 1924 and subsequently used it in my own clinic at the University of Nebraska College of Medicine.

There seems to be one insurmountable difficulty with the procedure. It is true that many enuretic persons, if not all, suffer from a loss of confidence in their ability to control their urinary bladders. The "start-stop" method, in some cases at least, convinces these youngsters that they do have voluntary control if they choose to exercise such control. There was not a single child in my clinic who ever missed an opportunity to express pride and happiness in his achievement, and even bad enuretic patients went from one to several weeks without "accident."

To my chagrin, however, these boys and girls soon began to return in increasing numbers with downcast features, each with the same story. They were so enthusiastic about the procedure that they commenced to practice it in their sleep. In the group was 1 boy aged 11 who was suffering from diurnal enuresis and who was so preoccupied with resentment toward one of his teachers that he began unconsciously to "start and stop" while daydreaming in the classroom. He "guessed" forlornly that he had more confidence in starting than in stopping. His enuresis cleared up shortly after he had been transferred from parochial to public school.

The current belief among pediatricians that enuresis as a bad habit has greater social than medical implications is, in my opinion, logical indeed.

HERMAN M. JAHR, M.D., Omaha.

SUCROSE TOLERANCE TESTS

To the Editor:—In regard to the item on "Sucrose Tolerance Tests," published in Queries and Minor Notes in THE JOURNAL, Sept. 14, 1946, page 116, in which it is stated that sucrose tests have not been done in large enough numbers for statistically significant normals to be established, we think it might be of some help to your correspondent to offer you the results of our investigations on the effects of the ingestion of 100 Gm. of sucrose on the blood sugar and levulose levels in 100 normal persons. These results were communicated to the Physiological Society of Great Britain in 1942. As wartime conditions prevented publication of the complete details, we attach a summary of our results.

Average Normal Values and Standard Deviations After Ingestion of 100 Gm. of Sucrose

Fifty Male and Fifty Female Controls, in Milligrams per Hundred Cubic Centimeters

	Male		Female	
	Blood Sugar	Blood Levulose	Blood Sugar	Blood Levulose
Fasting	83±10	2.6±0.58	78±10	2.2 ±0.3
¾ hr. after sucrose..	123±24	6.6±1.5	110±19	5.5 ±1.2
1½ hr. after sucrose..	89±17	6.7±1.4	84±18	6.2 ±1.2
2 hr. after sucrose....	78±15	5.3±1.0	77±15	5.25±1.1
2½ hr. after sucrose..	77±12	3.9±1.0	73±13	3.9 ±1.0

We have since shown that the sucrose test is a reliable test of liver damage (*Brit. M. J.* **1**:212 [Feb. 12] 1945. Some Early Effects of Exposure to Trinitrotoluene, *Brit. J. Indust. Med.* **2**:74, 1945).

ENDOCRINE THERAPY IN MALE STERILITY OF NONENDOCRINE ORIGIN VALUELESS

To the Editor:—Despite the fact that reputable clinicians are now in accord that endocrine treatment of male sterility of nonendocrine origin is futile, such therapy is still widely in vogue. Apparently, even a number of honest physicians are still "trying out" glandular injections for azoospermia and severe oligozoospermia with no endocrine basis whatever. Much of the blame for continuing this therapy undoubtedly falls on the shoulders of some pharmaceutical houses, still advertising treatment of male sterility by hormone injections, etc., based on so-called "clinical reports." On close scrutiny of these "clinical reports" one finds that they consist of either old outdated articles or reports from some physicians whose papers give mute evidence of unscientifically controlled experiments, wild imagination, wishful thinking and probably even microscopic mirages.

In an attempt to reach the masses of physicians to forestall further useless therapy, a few brief notes from a paper to be published in detail elsewhere follow.

On my return from service in 1946, in a follow-up study, I contacted many of my former childless couples and asked to see them. In the years that had elapsed, some had had babies and others had not. Most interesting were the cases of 36 husbands who had received endocrine treatment in my absence. Previouly, I had given each of these men little or no hope for future procreativity. Each had been personally diagnosed as sterile, or so extremely oligozoospermic as to be practically sterile. For example, in this drastic oligospermic class the general status of the semen was such that the observer had to search under the high power for a few spermatozoa—living, dead or otherwise. *In none of these specimens had there been a count of more* than 5 million spermatozoa per cubic centimeter.

In the follow-up, attempts were carefully made to obtain information regarding the type, amount and duration of therapy. It is significant that a number of the physicians contacted, reported to me that they had treated the particular patient in question only as a result of urging from the patient himself or the patient's wife. It was found that all types, doses and combinations of endocrine medicaments had been used, including large doses of estrogens and androgens (now known to be sperm-inhibiting). Treatments lasted on the average about three months.

In the process of rechecking, each of the 36 passed a properly collected specimen. I, personally, examined each semen. The findings were as anticipated. Nine men who had been completely azoospermic were still azoospermic. Twenty-five with severe depletion of spermatozoa were practically unchanged—in not one of these men was any appreciable evidence of improvement found. Two men, in whose semen I had found in 1943 an occasional sperm cell, now showed complete azoospermia following an intensive course of testosterone treatment.

It cannot be too strongly emphasized that the cause of the vast majority of cases of infertility in the male has not yet been determined. Most of them in private practice are nonobstructive, *nonendocrine and without history* of scrotal swelling following mumps. Lowered male fertility, aside from those instances in which a definite cause can be elicited, may simply be a congenital failing. Certainly, endocrine therapy where there is no evidence of endocrine deficiency is foolhardy and at times even deleterious.

May I suggest that restraint be practiced in the treatment of male infertility until some form of proved therapy, supported by reputable scientists, is made available. In this connection, based on the original investigations of McClean and Rowlands (England) with the enzyme hyaluronidase, Kurzrok in this country has reported preliminary experiments using this substance in male infertility which bear watching.

Abner I. Weisman, M.D., New York.

APPARENT SENSITIVITY TO AMIGEN

To the Editor:—I am writing you concerning the clinical report by Harris, Gordon, Gray and Barton on "Apparent Sensitivity to Amigen," which appeared in The Journal, November 30, page 785.

It seems to me not only that this report lacks scientific objectiveness but that the authors have certainly not established any *proof of sensitivity to Amigen.* No evidence was adduced that this reaction was not based on the administration of pyrogen or contaminated solution. There was no culture of the Amigen solution reported or any other study of the material that they gave. The conclusion certainly is not warranted by the evidence which the authors present that the reaction was due to a foreign protein inherent in the manufactured solution. The descriptive literature of the product states that every batch of this material is tested on guinea pigs for its anaphylactogenicity and the absence of protein very carefully established. Since the authors of this report made no effort to prove that protein was present, it seems hardly justified to attribute the reaction to this cause without proof in a case so otherwise involved.

Casein hydrolysates are excellent culture mediums, and reactions to such solutions may occur as a result of contamination or the presence of pyrogens due to poorly washed equipment. The report as an instance of apparent sensitivity to Amigen seems unwarranted by the evidence submitted.

Physicians, I am sure, are deeply interested in proved instances of sensitization or other proved reactions to casein hydrolysate itself, but poorly documented papers of this type are untimely and only confuse the subject by attributing reactions of all types to sensitization without adequately investigating other causes.

H. G. Poncher, M.D., Chicago.

DEMEROL IN ITALY

To the Editor:—The controversy with regard to Demerol appearing in the Correspondence department of The Journal of September 7 has been followed attentively by the Italian medical public.

Demerol in the form of the hydrochloride of methyl-phenyl-piperidyl ethyl carbonate is well known in Europe and has been largely used in Italy. Controversies such as now appear in The Journal on the more or less narcotic character of the drug have happened in Europe. In Germany it was finally decided to list the new preparation among the narcotics and to impose the same regulations on the medical practitioner as were in force for morphine. But in Italy the product has never been classed as a narcotic, and till a few months ago it could be obtained without license from the druggist, as opposed to narcotics. Actually in Italy the product commands a very high price per vial in the black market, but no special prescription (as in the case of morphine) is required from a medical practitioner.

In spite of all the laboratory assertions, use of the drug from 1939 to 1945 has taught us that addiction is also produced with it. We are therefore fully in accord with the authoritative declaration of Dr. Anslinger. But this addiction is less troublesome than that due to morphine, in that it is not so general. Patients with renal colic have come happily through the operation and recovered quickly from "addiction" though used to ten or more vials of Dolantin per day, a phenomenon that is never shown by morphine. Probably it is really due to the chemical relationship with atropine that addiction to it is "selective" among the patients.

Naples, Italy.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Privileged Communications: Applicability of Statute to Physicians and Inmates of State Hospital for Insane.—Claimant, a minor, by his guardian, filed suit against the state of New York for damages arising from his having been assaulted by a fellow inmate at the Harlem Valley State Hospital, an institution owned and operated by the state of New York for the observation, treatment and care of the mentally ill. The case was heard in the court of claims of New York.

The claimant and one Benturira had been patients in the Harlem Valley State Hospital for some years prior to the date of the assault, the claimant with a diagnosis of psychosis with mental deficiency and Benturira with a diagnosis of psychosis and epileptic clouded states. On the date of the assault, both individuals had been confined to their beds by means of restraint sheets in the restraint room, which formed part of the ward reserved for the care of the more violent inmates. At about 1:45 a. m. Benturira succeeded in breaking out of his restraint sheet and brutually attacking the claimant, who was still confined and unable to defend himself. As a result of this attack the claimant suffered a fractured nose and various bruises and was rendered permanently blind. At the trial claimant endeavored to introduce into evidence the hospital record of Benturira, contending that this record would clearly establish that the officers and employees of the hospital well knew that Benturira was of a violent and assaultive disposition and that he had escaped from restraint sheets on several occasions. The conclusion sought to be drawn was that in the light of this knowledge the officers and employees were negligent in permitting these two inmates to be confined in the same room without special precautions. The state objected to the introduction of this record on the ground that its contents were privileged communications between the hospital physicians and the patient, within the meaning of section 352 of the civil practice act.

Section 352 of the civil practice act provides, in substance, that a physician shall not be allowed to disclose any information he acquired in attending a patient in a professional capacity and which was necessary to enable him to act in such capacity. It has already been held, the court pointed out, that this professional relationship does not exist between the official physicians of a state hospital and its inmates. In Wigmore on Evidence (ed. 3, section 2285) four fundamental conditions necessary to the establishment of a privilege against the disclosure of communications are set forth: (1) The communications must originate in a confidence that they will not be disclosed; (2) such confidence must be essential to the satisfactory maintenance of the relationship; (3) the relationship must be one which ought to be sedulously fostered; and (4) the injury resulting from disclosure must be greater than the benefit disclosure would afford in disposing of litigation correctly. The privilege here asserted by the state, said the court, fails to meet any of these tests excepting the third. It is extremely dubious that John Benturira considered any communications to the hospital physicians, or any observations made by them, as confidential, and it is difficult to see how either confidentiality or its lack would affect the relationship between such physicians and a mentally deficient patient. Further, any conceivable injury to such relationship resulting from the disclosure of the records at this trial is certainly outweighed by the value of such disclosure in arriving at an informed decision in the case.

Continuing, the court said that, even assuming that the privileged relationship of physician and patient might exist in such an institution, an exception to the privilege appears to be provided by section 84 of the mental hygiene law. This section, after discussing the type of records which must be made relative to the inmates of such institutions, provides:

> Such record shall be accessible only to the director and such officers and subordinates of the institution as he may designate and to the commissioner and his representatives, except on the consent of the commissioner or an order of a judge of a court of record.

Certainly, said the court of claims, in the light of this section, the hospital records of an inmate of a state institution for the care of the mentally ill enjoy no such absolute privilege against disclosure that only the patient can waive it, as is now contended by the state. The section clearly provides that such records may be disclosed to any one, without consulting the patient, on the consent of the commissioner or on the order of a court of record. This court made an order on the claimant's motion directing the state of New York through its physicians and employees to submit to an examination before trial with respect to, among other things, the diagnosis, treatment, care and conduct of John Benturira and also directing the state to submit, for discovery and inspection by the claimant and his attorneys, substantially all of its record relating to the same matter. This order of examination and discovery was such an order of a court of record as is contemplated by section 84 of the mental hygiene law. At the time when this order was under consideration the state not only did not oppose but consented to those portions thereof concerning the examination and inspection with respect to Benturira and did subsequently submit to a lengthy and detailed examination before trial with respect to the diagnosis, treatment, care and conduct of John Benturira and did submit for inspection all of the now disputed records concerning him. No question of privilege with respect to such records was raised by the state at the time when the order was granted, no appeal was taken from the order, and no objections to any questions concerning Benturira were made during the examination. Such conduct on the part of the state would seem to amount to a waiver of the right to claim the benefit of the privilege. It seems adequately established that waiver of the privilege may be implied as well as expressed; that it may be implied from conduct not only at the trial but also in an examination preliminary thereto; and that voluntary disclosures on such a preliminary examination may be given the same effect as formal waiver on the trial. Accordingly the court of claims concluded that the relationship of physician and patient does not exist between state hospital physicians and mentally deficient inmates to the extent that communications between them are absolutely barred from disclosure by section 352 of the civil practice act and that such privilege as may exist under some circumstances is limited by section 84 of the mental hygiene law. This and other contentions having been resolved in favor of the plaintiff, judgment was entered therefor.—*Scolavino v. State, 62 N. Y. S. (2d) 17 (N. Y., 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Jan. 11, page 125.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part III.* Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Los Angeles, April 11-12. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York.

American Board of Dermatology and Syphilology: *Written.* Various centers, March 24. Final date for filing application is Feb. 17. *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Written.* Chicago, March 17. *Oral.* Chicago, April 24-26. Final date for filing application is Feb. 15. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Neurological Surgery. *Oral.* Examination to be given during the Summer. Applications for examination will be accepted until Feb. 15. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago.

American Board of Obstetrics and Gynecology: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: *Oral. All Groups. Parts I and II.* Chicago, October 1947. Final date for filing application is March 1. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Me.

American Board of Orthopedic Surgery: Applications for the next examination for Part I will be accepted until Feb. 1. Sec., Dr. Francis M. McKeever, 1136 W. Sixth St., Los Angeles 14.

American Board of Otolaryngology: *Oral.* St. Louis, April 16-19. Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

AmericanBoard of Pathology: Philadelphia, June 3-4. Final date for filing application is April 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kings Highway, St. Louis 10.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. *Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled.* Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

16:597-670 (Oct.) 1946

Present Status of Rh Factor. P. Levine.—p. 597.
Contrast Coloring of Media by Dyes in Growing Tubercle Bacilli. Effect of Dyes on Growth of Tubercle Bacilli. H. J. Corper and M. L. Cohn.—p. 621.
*Reactions of Tissue to Cold: Pathology of Frostbite, High Altitude Frostbite, Trench Foot and Immersion Foot. N. B. Friedman.—p. 634.
Cirrhosis of Liver and Diabetes as Related to Hemochromatosis. P. A. Herbut and H. T. Tamaki.—p. 640.
Glycogen Storage Disease of Heart. J. L. Haymond and A. S. Giordano.—p. 651.

Reactions of Tissue to Cold.—Friedman discusses the *pathologic anatomy and pathogenesis* of local injury due to cold on the basis of a study of material collected at the Army Institute of Pathology during World War II. Essential dissimilarity between the lesions of trench foot and of high altitude frostbite was not found. Agglutinative thrombosis resulting in ischemic gangrene can account for the most severe lesions, but some of the changes, particularly those in lipoid rich tissues, may be due to cold directly.

Progressive Recurrent Dermatofibroma (Darier Ferrand): Anatomoclinical Study. O. G. Costa.—p. 432.

Eczematous and Pigmentary Lichenoid Dermatitis.—Wilson reports more than 300 cases of lichenoid dermatitis. The disease is protean in its manifestations. At first it was thought that it arose only in New Guinea, but it was observed also in the Mediterranean region. The eruptions can be divided into the dry type, comprising approximately 20 per cent of the cases from the Southwest Pacific, and the exudative type, comprising 80 per cent. Either type may be mild or severe, and both may present complications. The two types may be present in the same person and at the same time. In some cases the lesions first are dry and then become eczematous and again are dry. The cause is not known, although several factors are probably involved, including low vitamin intake, especially vitamin A, quinacrine hydrochloride (atabrine) and allergy. It is believed that vitamin A deficiency predisposes to the disease but that quinacrine hydrochloride is the major factor.

Archives of Ophthalmology, Chicago

Exposure and Fixation of Eye in Early Days of Cataract Extraction. *B. Chance.—p. 484.*

Digitalis Poisoning.—Wagener and his associates observed digitalis poisoning in a man aged 50 who came to the Mayo Clinic because of poor vision, generalized weakness, nausea and vomiting. Two or three months previously he had had extrasystoles and had been given "leaf medicine" one tablet four times daily for about two weeks. After two weeks his medicine had been changed to another "green digitalis tablet"; he had taken one tablet three times daily for six weeks. About two weeks before he came to the clinic his appetite had become poor and he had vomited several times. He had noticed that lights had become yellow and that green grass had assumed a yellow tint. His vision had also become blurred, and he had found himself unable to read. *Bilateral central scotomatous defects* were demonstrated in the fields of vision, and complete heart block was demonstrated by electrocardiography. The vision returned to normal in about five weeks without treatment except for withdrawal of the digitalis *and increasing the amount of fluid ingested by mouth.*

Rh Antibodies in Newborn and Pathogenesis of Erythroblastosis.—Hill and Haberman report 10 cases of erythroblastosis in newborn infants which showed relatively good correlation between severity of the disease and antibody titer as demonstrated by the developing test. By using antihuman globulin serum as a routine developing test in suspected Rh isoimmunizations the advantages of this test in respect to its sensitivity for incomplete antibodies were confirmed and its usefulness in demonstrating Rh antibody in the serum of mother and infant was proved. This test also detects specific Rh antibodies not demonstrable with agglutinating or blocking tests. The developing test as applied to the demonstration of adsorbed antibodies on fetal erythrocytes is suggested as a diagnostic test for erythroblastosis. Immediate and adequate transfusion of Rh-negative blood is recommended for hemolytic disease of the newborn. Breast feeding is contraindicated when Rh antibodies can be demonstrated in the maternal or fetal serum or adsorbed on fetal erythrocytes.

Blood and Bone Marrow in Infectious Mononucleosis.—Limarzi and his associates report 25 cases of infectious mononucleosis in 18 men and 7 women between the ages of 13 months and 35 years. The characteristic finding in the differential count was the large number of abnormal "leukocytoid" lymphocytes in the peripheral blood. In spite of this the bone marrow showed a lack of lymphocytic infiltration and replacement of the marrow by lymphocytes seen in cases of lymphatic leukemia. The bone marrow revealed a myeloid hyperplasia and immaturity. Either the "toxic agent" acts on the bone marrow to produce a myeloid hyperplasia and suppresses their delivery to the peripheral blood or the suppression of the myeloid tissue results in a myeloid hyperplasia. Sternal puncture is of aid in the differential diagnosis of benign and malignant types of lymphocytosis.

Multiple Sclerosis.—Reese reports 241 cases of multiple sclerosis, 65 of which were studied over a long period. Blood studies revealed a definite tendency to a higher eosinophilia, though allergic signs in history and clinical examination were lacking. Practically all the patients presented a starting hypoprothrombocytopenia. The anticoagulant Dicumarol (3-3'-methylene-bis-[hydroxycoumarin]) was used in 28 cases for from two months to over one and a half years, but no objective improvement was seen. Horton's histamine treatment has given satisfactory results in early and remittent cases of multiple sclerosis. Each case must be tried on rationally acceptable therapeutic schemes, since no specific therapy is available.

Vascular Lesions of Brain Stem and Cerebellum.—Skogland reports 8 cases of clinical syndromes associated with thrombosis of arteries supplying the brain stem and cerebellum in patients who were admitted to the Charity Hospital in New Orleans during the period 1935 to 1943. There were 4 patients presenting the syndrome of the posterior inferior cerebellar artery, 1 with thrombosis of the vertebral artery and 3 with thrombosis of the basilar artery. Cases of thrombosis of the anterior spinal artery and of the superior cerebellar artery are reported in the literature, but there were no admissions of persons thus affected to the Charity Hospital. The close correlation between clinical symptoms and distribution of pathologic changes is emphasized.

*Plasma Quinacrine Concentrations Attained by Subjects Taking 0.1 Gm. of the Drug Daily. E. R. Becker, C. S. Burks and E. Kaleita.—p. 165.

Malaria Mortality and Morbidity.—Faust and his associates present the yearly assessment of the status of malaria in the United States for 1944, based on replies received from a questionnaire sent to the bureau of vital statistics of the forty-eight states. The picture continues to be more favorable every year. The endemic regions in the South have shrunken within the last five years. Malaria deaths outside the South are becoming less frequent, and of those certified the majority have resulted from exposure in the South or outside the United States. However, civilian infections reported to state boards of health do not adequately reflect the malariousness of the respective area. Few states have records approximating the actual number of cases of malaria existing within their area. Few state agencies carried out malaria or antimosquito campaigns in 1944. The discharge to civilian life of military forces with recurring vivax malaria may constitute a serious public health hazard in areas where Anopheles mosquitoes are allowed to breed in numbers, unless antimosquito campaigns continue to be vigorously prosecuted.

Plasma Quinacrine Concentrations.—Military personnel in the vicinity of Ledo, Assam, India, were placed on a suppressive quinacrine regimen of 0.1 Gm. daily (0.7 Gm. per week). Twenty-one volunteers were selected as subjects whose quinacrine concentration of the plasma could be followed. None had taken quinacrine previously. The mean plasma quinacrine levels of 14 of these 21 stabilized within two weeks at values ranging from 21.3 to 26.0 micrograms per liter. Seven others attained somewhat lower means, apparently because this group contained 4 persons who might be called "poor absorbers." None of these 21 exhibited extraordinarily high levels, but in other studies a number of such persons were encountered and most of these showed extreme coloring of the skin.

*Porphyria: Neuropsychiatric Aspects in Case of Negro. J. M. Schneck.—p. 432.

Neuropsychiatric Aspects of Porphyria. — Schneck reports that a Negro soldier aged 40 began unexplainably to experience anxiety when in crowds. Later he developed impairment of vision. Concurrent with episodes of weakness accompanied with impaired vision there would be excretion of urine which appeared a deep orange and at times red. Constipation developed. Neurologic examination revealed generalized hyperactive reflexes, except for the absence of knee jerks, which reappeared on repeated tapping of the tendon. An especially interesting fact in the reported case is the sequential relationship of the anxiety episodes to the onset of the physical manifestations of porphyria.

*Evidence of Citric Acid Synthesis in Human Subjects. Juniata E. Strom and Milicent L. Hathaway.—p. 337.

Reproductivity of Rats Given Caffeine.—Albino rats were given a sweetened caffeine beverage as their sole source of fluid throughout their reproductive period. The reproductive capacity as judged by the number of litters and number of offspring was not impaired by the daily ingestion of caffeine.

Evidence of Citric Acid Synthesis in Human Subjects.—Strom and Hathaway maintained 3 normal women for forty-five days on a synthetic diet free from citrates and for twenty-one days on a controlled natural food diet of similar nutritive value but supplying approximately 797 mg. of citric acid daily. Individual variations in daily citrate excretion of 300 to 500 mg. were found on both the synthetic and the natural food diets. These and other observations convinced the authors that citrates in the urine are largely synthesized by tissues rather than coming from body stores.

Efficiency of Animals to Produce Human Food.—Maynard shows that, while the feeding of animals results in a concentration of food nutrients into more palatable and more digestible forms for human use, it also involves wastage. Adjustment of livestock production in the interests of better nutrition for more people should recognize differences among species and feeding operations with respect to (*a*) efficiency of human food production, (*b*) consumption of foods directly useful to man and (*c*) nutritive value of the animal product. Taking these factors into account, it is concluded that milk production should have first priority on feed supplies available. Butter production rates the same priority only to the extent that the skim milk is recovered for human use. Egg production should be ranked above pork production, but broiler production deserves only a low rating. To the extent that beef cattle and sheep utilize range and other roughage not available to dairy cattle, their production should have a high priority rating, but heavy fattening of meat animals is an inefficient use of the basic food supply in relation to human needs.

Histoplasmin Sensitivity. — Christie and Peterson performed more than 2,000 histoplasmin tests in various age groups and from a considerable area of the country, including Tennessee, various of the Southeastern states, Pennsylvania, New Jersey and New York. The age relationships in the development of histoplasmin sensitivity, pulmonary calcifications and tuberculin sensitivity and the geographic variations of histoplasmin sensitivity, pulmonary calcifications and tuberculin sensitivity are presented. The significance of histoplasmin sensitivity as demonstrated in these studies and the significance of these studies in relationship to the study of the epidemiology of tuberculosis are discussed.

Kernicterus in Erythroblastosis Fetalis.—Vaughan reports 72 cases of erythroblastosis fetalis with 25 deaths. Necropsy was performed in 21 cases. Four of the surviving patients had mental retardation. An unfavorable outcome was associated with the clinical or pathologic signs of kernicterus in 20 cases. In 12 cases of kernicterus there were also focal pulmonary hemorrhages, and these infants displayed a striking clinical picture made up variously of drowsiness, spasticity, opisthotonos, signs of motor irritability, respiratory irregularity, pulmonary rales and rhonchi, and bloody discharge from the upper respiratory tract. Clinical and pathologic features of the cases in which kernicterus was present suggest that blood destruction is not the primary determinant of nuclear damage. Immaturity, vascular injury, altered antigen-antibody reactivity and intrapartum transfer of antibody may play possible roles in the pathogenesis of kernicterus.

Pertussis Vaccine.—Waddell and L'Engle administered deep subcutaneous injections of 0.5 cc. of a vaccine containing 40,000 million killed whooping cough bacilli (phase I) to 129 infants 1 week of age, with a second dose of 1 cc. at 1 month of age and a third dose of 1 cc. at 2 months of age. In order to determine the advisability of a booster dose, 1 cc. of vaccine was administered to 50 previously vaccinated infants at approximately 6 months of age and the agglutinin titer determined one week later. Results showed that it is advisable to start immunization against pertussis from six weeks to two months after birth. A booster dose at seven to eight months may well be given as an added measure of precaution. A satisfactory immune response can be regularly expected when a first dose of pertussis vaccine is administered in the neonatal period. Pertussis vaccine can be safely administered at this early age period without fear of disagreeable local or systemic reactions.

Surgical Treatment of Ascites.—In treating ascites Crosby and Cooney insert a glass button into the lower rectus sheath so that ascitic fluid may drain from the peritoneal cavity into the subcutaneous tissues and be absorbed as edema fluid. Five cases of Laënnec's cirrhosis of the liver and 1 of chronic constrictive pericarditis are reported, in all of which the ascites was treated by the insertion of the button. The rationale for the use of the button is to obviate repeated abdominal paracenteses. Its main advantage over previous surgical measures is its simplicity of application. An additional value is that it returns to the patient his own ascitic fluid together with its protein content as a constant slow clysis as long as the fluid is formed.

Strangulation of Bowel by Adhesive Band.—p. 628.
Ewing Tumor of Clavicle.—p. 630.

Penicillin in Subacute Bacterial Endocarditis.—Massell and Jones present the histories of 2 patients with subacute bacterial endocarditis who were cured by penicillin. The resistance to penicillin of the causative organism in 1 case was greater than that of any other successfully treated case reported in the medical literature. The correlation of the clinical picture with the penicillin sensitivity of the causative organism is of interest: 1 patient was extremely ill, and the causative organism was extremely sensitive to penicillin; the other was mildly ill, and the causative organism was relatively resistant to penicillin.

Thrombin and Fibrin Foam in Suprapubic Prostatectomy.—Quinby dissolves thrombin powder in about 10 cc. of isotonic solution of sodium chloride and immerses into it pieces of foam about 1.5 to 2 cm. square. These pieces are then placed in the cavity of the prostate after suprapubic prostatectomy. This method of hemostasis was employed in 40 cases, and it is noteworthy that secondary bleeding occurred in none of the cases. Lavage of the bladder could be abandoned early, and the wound was healed and dry and voluntary urination had been resumed, on the average, eleven and a half days after operation.

Increase in Diphtheria.—A higher incidence of diphtheria in North Carolina than in the United States as a whole is ascribed by Stevick to the fact that North Carolina has an inadequately immunized population. The major defect in the North Carolina immunization program is that the number of infants receiving a complete primary immunization is inadequate and not that the immunizing agent is ineffective or that new and more virulent strains of the diphtheria organism have developed. It is suggested that immunization of all infants at 6 months of age, followed by the administration of booster doses of the immunizing agent at 1 and 5 years, would afford more adequate protection.

Effect of Immunization on Epidemic Influenza.—During an epidemic of influenza at Duke University 85 male students were vaccinated after the onset of the epidemic, while 1,956 other male students were not immunized. In the vaccinated group the incidence of influenza was 2.3 per cent, while in the control group the incidence was 8.6 per cent. Furthermore, some of the control group developed complications. Broadbent and Menefee conclude that vaccination affords protection against influenza, and they suggest that results might have been even better if immunization had been given somewhat earlier.

Curare in Abdominal Surgery.—Howard used curare in conjunction with ethylene, cyclopropane, ether and sodium pentothal in anesthetizing 208 patients who underwent abdominal operations such as appendectomy, colostomy, bile duct exploration, hemorrhoidectomy, herniaplasty and hysterectomy. From 1 to 7 cc. of the curare *preparation intocostrin* was administered in divided doses. Curare provided excellent relaxation without undue risk. There was no operative mortality.

Cellophane Wrapping and Ligation of Patent Ductus Arteriosus.—Poppe thinks that cellophane wrapping and ligation is the simplest and safest method of dealing with a patent ductus arteriosus. A physiologically reactive variety of cellophane such as polythene should be used in preference to an inert type. The optimal time for ligation appears to be immediately after the recovery from an acute episode after six or eight weeks of penicillin therapy, before the patient has another attack.

Delayed Allergic Reaction to Penicillin Treated with Procaine Intravenously.—Rosellini and Van Rooy report that a man aged 28 developed a *generalized itching rash* and arthralgia more than a week after he had been given several injections of penicillin in oil and wax for an infraorbital abscess. After conservative methods had failed to counteract the rash, 1 Gm. of procaine hydrochloride was dissolved in 500 cc. of isotonic solution of sodium chloride and was given intravenously over a period of two hours. *Before the infusion* was completed the patient felt better. The urticaria was rapidly disappearing. The joint symptoms were somewhat alleviated.

Brucellosis.—Hernández Morales reports 8 cases of acute and 4 of chronic brucellosis. The electric refrigerator probably plays a part in the rising incidence of brucellosis in Puerto Rico. Our grandfathers had to boil their milk before drinking it so as to prevent its souring and in this way unwittingly combated the disease. Today, milk can be easily preserved raw; moreover, raw milk is cheaper than pasteurized and is served almost everywhere, especially in restaurants It is also utilized in the making of cheese. No law forbids its use unpasteurized Unless preventive measures are established, the disease will become widespread

Vaginal Cell Examination.—Ayre reviews observations on 2,320 gynecologic cases in which a cytologic study for malignant growths was made Genital cancer has been diagnosed by cytology and confirmed by biopsy in 202 cases. The centrifuge technic and the glycerin method for mailing cytologic specimens are briefly described A group of preclinical, asymptomatic cases has been detected by routine cytologic tests, and a new cell complex has been described in cases showing a linkage of abnormally high cornification (estrogen) with a measurable thiamine deficiency These cases have been grouped as precancerous

Streptomycin in Primary Tularemic Pneumonia.—Atwell and Smith present the histories of 2 Negro boys aged 13 and 17 The two lived in the same room and were exposed to dog ticks and to rabbits brought into the house by their dogs. The date of the exposure could not be determined and no local dermal lesion could be found, but the serums agglutinated tularense antigen The first patient was much more seriously ill than the second and almost moribund at the time streptomycin therapy was started Both patients seemed to improve clinically after about two days of streptomycin In the case of the massive pleural effusion, it seemed that the intrapleural streptomycin was very efficacious in eliminating the organism and in stopping the formation of fluid The doses of streptomycin were rather large, but it was felt that the highly fatal primary pneumonic form of the disease would require more intensive treatment than the milder ulceroglandular type of tularemia

Radiologic Study of Hemophilia.—Ostro and Macht describe investigations which revealed that irradiation with x-rays noticeably shortens the coagulation time of blood specimens from animals and human beings in vitro Two hemophilic patients treated with x-rays over the splenic region showed considerable shortening of coagulation time for some time afterward The authors hope that this preliminary report will stimulate further investigation

Appendicitis.—Moses thinks that appendicitis in its usual form is initiated by obstruction of the lumen of the organ If this obstruction is not relieved, either spontaneously or by surgical intervention, there follows venous obstruction with outpouring of an edematous exudate It is this phase which is usually seen when the viscus is described as "red hot" During this stage the wall comes to act as a permeable membrane to the luminal bacteria with the possibility of a "localized peritonitis" in the absence of demonstrable perforation. If this process of venous obstruction is allowed to persist, arterial occlusion by spasm, extrinsic pressure on the vessel or thrombosis will supervene, with resultant perforation or gangrene, the extent of the necrosis depending on the size of the occluded vessel. The role of bacteria appears to be solely that of a secondary invader.

Subtotal Esophagectomy in Cicatricial Obliteration.—Three patients with cicatricial obliteration of a large portion of the esophagus as a result of chemical burns were treated by radical esophagectomy In 2 of these the upper limit of the lesion was low enough to make it possible to perform the anastomosis a short distance below the arch of the aorta In the third the proximal extent of the obstructed area was so high that the anastomosis when completed lay behind the level of the jugular notch In this case a subtotal esophagectomy was performed All 3 patients made a complete recovery. Sweet concludes that in cases of intractable stricture of the esophagus resulting from chemical burns an esophagectomy followed by a high intrathoracic esophagogastric anastomosis is superior to any form of external esophagoplasty.

Gastric Cancer: Resectability and Mortality.—Maimon and Palmer analyze the present status of the surgical treatment of gastric cancer with respect to exploratory laparotomy, resectability and postoperative mortality on the basis of 576 patients with gastric carcinoma who were examined over a seventeen year period at the University of Chicago Laparotomy was carried out on 389, or 83.5 per cent, of the 466 patients who followed the advice given The remaining 16.5 per cent were inoperable The resectability rate in the 389 submitted to exploration was 52.1 per cent The resection survival rate in the 203 patients undergoing resection was 73.7 per cent. The mortality in unselected cases of partial resection was 22.6 per cent before 1940 and 16.3 per cent after 1940 The percentage of patients considered operable is increasing; the resectability rates are becoming higher and the postoperative mortalities are decreasing in spite of the greater incidence of complicated and extensive operations Nevertheless the outlook for prolonged survival continues to be limited

Bilateral and Multiple Ruptured Disks.—Echlin and his associates review observations on 60 patients who were operated on for suspected herniation of a lumbar disk. One patient was found at operation to have three ruptured disks, 6 patients two herniated disks and 3 patients a bilateral herniation of an intervertebral disk requiring bilateral removal. In 2 other patients, from each of whom a ruptured disk had been removed elsewhere at the fifth lumbar level, a second herniated disk was found on the same side as the original exploration but in both cases at the interspace above. From another patient who had

had a negative exploration elsewhere at the third lumbar level the authors removed two herniated disks. In still another instance a herniated disk was extirpated at the fifth lumbar level on the left in a patient from whom a herniated disk had been removed elsewhere from the same interspace on the opposite side. Thus 6⅔ per cent of the patients had bilateral and 16⅔ per cent had multiple herniated disks.

Talc Granuloma.—Lichtman and his associates state that the tissue damage caused occasionally by talc is a heavy price to pay for the preservation of a pair of rubber gloves. Granulomatous lesions of the peritoneum, draining sinuses, scar nodules and malfunctioning intestinal stomas were found at secondary operations. Polarized light microscopy was of great value in identifying talc crystals and in studying the pathogenesis of talc granuloma. The authors think that talc granulomas would be recognized more frequently if there were greater use of polarized light microscopy.

Vascular Injuries in War. B. Bradford Jr. and M. J. Moore.—p. 667.

Dietary Deficiency in Pregnancy.—Vilter and his associates present cases which illustrate dietary deficiency in pregnancy. The cases show neuritis of thiamine deficiency in a woman aged 27, pellagrous glossitis in a mother aged 35 in the last trimester of her seventh pregnancy and riboflavin deficiency symptoms in the mother of 8 children during a period of lactation. The principles of treatment for nutritional disease occurring during pregnancy do not differ from those generally prescribed in nutritional deficiencies. They include a high caloric diet including from 120 to 150 Gm. of protein and adequate minerals and vitamins as well as synthetic vitamins directed at the more prominent symptoms and finally a natural source of vitamin B complex such as brewers' yeast, crude liver extract or wheat germ.

Gastric Carcinoma: Incidence and Diagnosis.—On the basis of studies on more than 500 cases of gastric cancer observed over a seventeen year period Maimon and Palmer conclude that the incidence of gastric cancer rises sharply with advancing age, approximately three fourths of the cases occurring after 50. Thus gastric cancer will increase in incidence as the average age of the population rises. Gastroscopy yielded the correct diagnosis in 84.6 per cent of the cases in which it was utilized. X-ray examination provided the correct diagnosis in 91.8 per cent of the cases so examined. "Dyspeptic" symptoms appearing in patients of the "cancer age" warrant prompt roentgenologic and gastroscopic study.

Transurethral Resection in Surgical Management of Cord Bladder.—Emmett and Dunn say that in 1944 one of them (Emmett) reported his experience in 20 cases of true cord bladder in which transurethral resection had been carried out. During the two year period from 1944 to 1946 transurethral resection was carried out at the Mayo Clinic on 45 patients who had neurogenic bladder resulting from injury or disease of the spinal cord. Thirty of these patients were suffering from a transverse lesion of the spinal cord, whereas the neurologic disease of the remaining 15 consisted of multiple sclerosis (7 patients), combined sclerosis (4 patients) and miscellaneous lesions of the spinal cord (4 patients). The authors present a number of illustrative case reports. They conclude that cord bladder no longer is a hopeless situation. Satisfactory vesical function can be restored by mechanical adjustment of the vesical neck and by teaching the patient to use unaffected muscles to aid him to void. Mechanical adjustment of the vesical neck is brought about by transurethral resection.

Tendon Transplantation in the Hand.—May describes and illustrates methods of tendon grafting in various regions of the hand. In stressing the importance of postoperative care he says that it is a common belief that motion, if started early, will prevent the adhesion of tendons, yet the opposite seems to be the case. Early motion favors adhesions not only because of irritation of the surrounding tissue but also because the vascularization of the tendon is disturbed. The author prefers the molded plaster cast splint. The hand is placed in such a position that the suture line is under a minimum of tension. After two and one-half weeks splint and dressings are taken off temporarily and the sutures removed. The forearm and hand are placed from now on daily in a warm saline bath, and active motion exercises are encouraged. The splint is reapplied after the bath. Three weeks after the operation the splint is discarded, and local heat, massage and passive exercises are added to the active exercises.

Tantalum in Tendon Reconstruction.—So many excellent jobs of tendon reconstruction have been spoiled by adhesions that Pearlman decided to use tantalum foil 0.00025 inch in thickness as an interpositional substance. This has often made it unnecessary to resect a tendon that is scarred and adherent. A tendon with raw surfaces was simply encased within tantalum foil and the foil held in place with catgut ligatures. The tantalum-wrapped tendon was then dropped back into its normal channel. The tantalum foil did not need to be removed. At the end of four to six weeks the tendon was "free" in its channel; the foil was found fragmented and adherent to adjacent tissues. The tendon itself was coated with a glistening layer of cells.

Therapeutic Agents in Plague.—Platzer states that sulfadiazine is the drug of choice in the treatment of plague. It must be given early in doses of 12 to 30 Gm. on the first day and smaller doses for twelve days after the temperature is normal. The best results have been obtained when the combined treatment with antiplague serum and sulfadiazine has been used. Antiplague serum and sulfadiazine are of value prophylactically in cases of exposure to plague.

Penicillin to Prevent Acute Otitis Media in Scarlet Fever.—Weiss and Manheims review observations of 239 cases of scarlet fever. They found penicillin greatly superior to sulfadiazine not only in the prevention of acute otitis media but also in the treatment of active otitic suppuration. Administration of 20,000 units every three hours for five to seven days is recommended.

Penicillin in Louse Borne Relapsing Fever.—According to Ingraham and Lapenta, louse borne relapsing fever appeared in Egypt after an absence of over twenty years. Penicillin was tried in a series of 52 cases, and 53 served as controls. The disease was relatively mild, with a fatality rate of 5 per cent in the untreated cases. The initial bout of fever lasted seven days on the average, with termination by crisis. The remission averaged eight days in length, followed by an abrupt recurrence in which the mean duration of symptoms was four days. A second relapse was unusual in this epidemic. Penicillin was given intramuscularly every three hours in 25,000 unit doses up to a total of 1,000,000 units. Cure was obtained in all 52 cases and no relapse followed, whereas in the controls relapse occurred in 87 per cent of the cases.

The Tubercle Bacillus and Chemotherapeutic and Antibiotic Action.—Corper and Cohn say that streptomycin administered in proper dosage is capable of retarding the growth of human tubercle bacilli both in vitro and in vivo. However, the concentration of streptomycin required to retard the growth of tubercle bacilli in vitro in good nutrient medium can be attained in vivo for only a brief period. Streptomycin is not tuberculocidal but produces its effects in vivo primarily as a retardant of the growth of tubercle bacilli when they are actively developing or reproducing. In clinical tuberculosis in man, the bacilli appear to reproduce and develop only at irregular periods undeterminable by clinical means and over long periods of time, and this reduces the applicability of a retardant without tuberculocidal action for use in human tuberculosis.

Oxygen Pressure Gradient Between Maternal and Fetal Blood.—Oxygen pressures were determined on sheep in the fetal umbilical artery, umbilical vein, uterine artery and uterine vein in the latter half of the gestation period. It was found that the pressure gradient favors the movement of oxygen from the maternal to the fetal blood.

Histamine in Allergic Conditions.—A man aged 34, who had a history of many allergic sensitivities (e. g. strawberries, tomatoes) presented the same clinical manifestations—generalized urticaria, rhinitis, sneezing, conjunctival hyperemia with profuse lacrimation and stomach discomfort with indigestion, burning, belching and nausea—after emotional excesses or contact with specific allergens. Brown thinks this case suggests that histamine plays a role in emotionally precipitated conditions that resemble allergies. Benadryl, which exerts an antihistamine action, was prescribed and it relieved the emotionally precipitated urticaria.

Resection of Head of Pancreas. C. A. Pannett.—p. 84.
*Brodie's Disease of Breast. D. Aiken.—p. 87.

Carcinoma of Esophagus.—Lewis reports 7 cases of esophagectomy with 5 recoveries. He describes a new operation of resection with immediate anastomosis for cancer in the middle third of the esophagus. After mobilization of the stomach by laparotomy, a right transpleural esophagectomy is performed, the stomach being brought up through the dilated hiatus, fixed at any required level in the right pleura, and an end to side esophagogastrostomy performed.

Brodie's Disease of Breast.—Aiken reports a case of Brodie's tumor in a woman aged 68. The tumor was removed, and there was no recurrence. The author stresses that the term "Brodie's tumor" should be reserved for large, excessively cellular and long-neglected fibroadenomas. The history of a preexisting breast tumor of many years' duration which at first grows slowly or not at all and finally in the late middle years increases rapidly in size is the outstanding feature of Brodie's tumor. The skin overlying the tumor is mobile, and the lymph nodes are not usually involved. Enlargement may be so great that ulceration of the skin occurs from pressure necrosis, and the foul, fungating mass suggests a carcinoma. Sometimes the correct diagnosis of an innocent large tumor is impossible until the breast is removed. One striking clinical feature is the excellent general condition of the patient.

*Sarcoidosis—A Manifestation of Tuberculosis. C. Cameron and E. K. Dawson.—p. 465.
Observations on Functional Heart Disease. I. G. W. Hill.—p. 485.
Ear-Pit (Congenital Aural and Pre-Auricular Fistula). I. Aird.—p. 498.
Tuberculosis in Sutherland with Special Reference to Surgical Tuberculosis. B. S. Simpson.—p. 508.

Sarcoidosis and Tuberculosis.—Cameron and Dawson report a case of pulmonary tuberculosis with pathologic changes in other tissues, which conformed with the accepted clinical and histologic features of sarcoidosis. The case is noteworthy because tubercle bacilli were recovered by culture in a sarcoidosis patient, for one of the salient characteristics of sarcoidosis is the difficulty with which Mycobacterium tuberculosis or any other criteria of the infection can be demonstrated. The history of the patient was a long one, *from the initial disturbance at the* age of 5 to her death at the age of 19. Signs and symptoms varied during this long period. Some lesions, such as the iridocyclitis and splenic enlargement, improved and disappeared; others, like the joint disorder, the kidney lesion and the slight, irregular, varying temperature, remained more or less constant.

Determination of Total 17-Ketosteroids in Urine Simplification of Method for Routine Use in Hospital Biochemical Laboratory. S. L. Tompsett and E G. Oastler.—p 281.
*Intussusception of Appendix D. C Miln—p 297.
Multiple Carcinoid Tumors of Bowel: Report of Case. A. Lyall.—p. *300*

Intussusception of Appendix.—*Miln* reports the case of a man aged 38 who in October 1945 had an attack of dysentery characterized by gastroenteritis, and severe griping abdominal pain. He was treated with sulfaguanidine, and the condition subsided, though he still complained of some ache in the right side of the abdomen which was worse during defecation. Palpation disclosed a tender mass in the right iliac fossa. Surgical intervention revealed an intussusception of the appendix into the cecum and partly into itself. The appendix was removed together with a small cuff of cecum.

Generalized Lymphatic Carcinomatosis (Cancerous Lymphagitis) of *Lungs, with Special Reference to Miliary Carcinomatosis and Syndrome of* "Granulie Froide." C. G. Lambie and J. Collier.—p 439.
Klinefelter Reifenstein Albright Syndrome H. F. Bettinger and B. Robinson—p 446
Toxoplasmic Encephalomyelitis, with Report of 2 Cases. E. G. Robertson—p. 449.

Costen's Syndrome and Head Pain.—Bell points out that Costen's syndrome is a hitherto unrecognized cause of vague head pain, which many patients have endeavored to describe with but little success. The symptoms are often bizarre. They usually arise because the mandibular condyle does not have a normal position in the articular portion of the mandibular fossa (glenoid fossa) throughout the various excursions of the mandible, these latter movements being controlled by the position of the teeth. The symptoms include dull pain within and about the ears; a "low buzz" type of tinnitus; a stuffy sensation in the ears; catarrhal deafness and dizzy spells which are relieved by inflation of the eustachian tubes; tenderness to palpation of the temporomandibular joints; sinus headache after sinus or ocular involvement has been found nonexistent; neuralgia; noisy, painful and either limited or excessive movement of temporomandibular articulation; burning or prickling sensation of tongue, throat and side of nose, and dryness of the mouth. Examination of the mouth and facial characteristics will generally more than hint at the loss of vertical dimension. Costen's syndrome is treated by increasing the maxillomandibular vertical dimension

**Effect of* Asbestos, and of Asbestos and Aluminum, on Lungs of Rabbits E J. King, J. W. Clegg and V. M. Rae—p 188.
Bronchiectasis and Atelectasis. Temporary and Permanent Changes. F. P. L Lander.—p 198.

Effect of Asbestos on Lungs of Rabbits.—The purpose of the experiments described by King and his associates was to test whether short fiber asbestos is *less damaging in the lungs* of the rabbit than is long fiber asbestos and whether metallic aluminum will suppress any toxic effect produced by fiber asbestos Four groups of animals were tested All groups showed a foreign body reaction in the lungs. In animals in the long fiber experiments there developed a *nodular* reticulinosis comparable with the experimental silicotic nodule. In animals in the short fiber experiment there developed a diffuse interstitial reticulinosis The addition of *aluminum* did not afford any benefit in any group.

*Intradural Lipoma of Cauda Equina. D. Furtado and Vasconcellos Marques.—p. 127.

Lipoma of Cauda Equina.—The lipoma observed by Furtado and Vasconcellos Marques in a woman of 56 is the eighth to be reported in the literature. The differential diagnosis from other intradural tumors is made by the history of slow evolution of the tumor, rheumatic-like pain in the legs, lack of radicular pain and progressive loss of walking in the absence of paralysis. There may or may not be blockage of the spinal canal. Treatment is early surgical removal in order to prevent compression of the spinal cord. Pure intradural lipoma is congenital. It is benign. Differentiation from fibrolipoma or liposarcoma is made only by microscopic study of the tumor.

Treatment of Hyperthyroidism with Thiouracil T. F. Bloem—p. 1039
Endemic Leprosy. P. H. J. Lampe—p. 1043.

Primary Carcinomas of Neck.—Wieberdink reports observations on 40 patients with branchiogenic carcinoma who were observed in the course of thirty years at the Antoni van Leeuwenhoek Hospital and compares them with 80 cases reviewed by Oliver in 1935. There were 34 men and 6 women, a sex ratio of 6:1, whereas Oliver observed a sex ratio of 9:1. The average age in Wieberdink's 40 cases was 66 years, in Oliver's cases 55 years. As in Oliver's patients, so also in those reviewed by the author, the first symptom was usually a painless swelling. There was a predominance in both groups of localization on the right side. Surgery followed by x-ray treatment has given lasting results. The prognosis in operable cases is definitely better than is usually assumed.

Investigations on Physiopathology of Erythrocytes: II. Reticulocytosis and Liberation of Erythrocytes from Bone Marrow. A Nizet—p. 590

Electrocardiographic Findings in Patients with Peptic Ulcer.—Ørning and his associates found in studies on 579 ulcer patients with a normal heart that vagotonia manifests itself by bradycardia, respiratory arrhythmia, prolonged PQ interval, and in 10 per cent of the cases by a characteristic electrocardiogram with high T waves in at least two leads. Bradycardia is the most frequent sign of vagotonia, occurring in about 50 per cent of the male and about 25 per cent of the female ulcer patients. Respiratory arrhythmia is seen in about 25 per cent of both sexes A prolonged PQ interval was noted in about 6 per cent of the men and about 3 per cent of the women. High T waves are also seen especially in men, often accompanied by an elevated ST line. These changes are especially pronounced in the younger age groups and are rare in patients over 50. The auriculoventricular conduction time shows increase up to and including the group of 50 to 59 years In ulcer patients with hemorrhage, myopathic abnormalities will be found in about 35 per cent. The cause of these alterations must be sought in a vasomotor reflex with consequent myocardial anoxemia. Atropine, owing to its parasympatheticolytic action, will cause the electrocardiographic changes evoked by the vagus to disappear. A prolonged PQ interval which does not become normal after *administration of atropine* must therefore be occasioned by factors other than vagotonia.

Book Notices

An Introduction to Essential Hypertension. By Richard F. Herndon, M.D., F.A.C.P. Fabrikoid. Price, $2.50. Pp. 88, with 7 illustrations. Charles C Thomas, 301-327, E. Lawrence Ave., Springfield, Ill., 1946.

Here is a concise, readable exposition of the known facts and latest theories on essential hypertension. This little book takes up in orderly fashion the normal regulation of blood pressure and the etiology and mechanism of hypertension, with its physiology, pathology, clinical aspects, prognosis, diagnosis and treatment. Nowhere else has the experimental work of Goldblatt, Page, Prinzmetal, Child, Lewis, Smith and a host of other careful investigators been so successfully yet briefly summarized. The pith of all these experimental data has been clearly and concisely stated and a reasonable theory of the etiology and mechanism of hypertension deduced. However, it is not definitely accepted by the author. The action of renin on preangiotonin to produce angiotonin (hypertension of Braun-Menendez) and destruction of the latter by angiotonase is briefly discussed. The controversial question of the role of renal ischemia in the production of hypertension is fairly stated. The author considers the etiology of essential hypertension still unknown but considers the disease as a "deep-seated, constitutional disorder woven into the very structure and personality of the individual and that it probably represents a composite of multiple factors."

The physiology of hypertension is briefly, probably too briefly, discussed. However, numerous references to pertinent literature are included, making it easily possible for the reader to extend his knowledge of this important aspect of hypertension. The author points out that arterial hypertension may be produced by three mechanisms: increased cardiac output, increased blood viscosity and increased peripheral resistance, but that in essential hypertension the first two are normal and that therefore the immediate cause of the elevated blood pressure must be increased peripheral resistance. He believes this is due to an inherent hypertonus of the arterioles, independent of the nervous system and organic changes in the vessel walls.

The pathology of hypertensive disease is treated simply and accurately, with emphasis on the cardiac and renal changes. It is the extent of the hypertensive lesions in the heart or kidneys which largely determines the clinical picture and the immediate prognosis.

The clinical aspects of the disease are tersely and accurately presented. Four color plates depict the funduscopic appearance in the four groups of the Wagener-Keith classification. The usual course of symptoms associated with so-called benign or essential hypertension is well outlined. The fulminating type, generally known as malignant hypertension, is rightly considered as differing only in the tempo of the disease and is correctly defined as those cases showing the characteristic lesion of papilledema.

According to the author, the prognosis depends on one minor and three major factors. He considers the height of the blood pressure a minor factor. The major factors are the extent of the arteriolar lesions, the degree of atherosclerosis and the cardiac status. The first can be estimated by the funduscopic examination and tests of renal function. The second is dependent more on the duration of the hypertension than on the height of the blood pressure. The third is determined by "the efficiency and sufficiency of the coronary circulation." Age and sex also influence the prognosis.

The diagnosis of hypertension is considered from both practical and theoretical standpoints. He classifies hypertension as essential, nephritic and symptomatic. Under essential he places benign and malignant hypertension. Nephritic is subdivided into parenchymal, vascular, perinephritic and ureteral. Symptomatic hypertension is considered to include physiologic, cerebral, cardiovascular and endocrine disturbances. The discussion of these various forms is brief but on the whole accurate.

The chapter on treatment is somewhat disappointing. One has been led to assume from the up-to-date material in the preceding chapters that the recently published results of surgical treatment would be as carefully analyzed, but such is not the case. The author states that "no treatment is yet known which has ever cured or arrested the progress of essential hypertension, although their temporary palliative value, especially in the early stages, cannot be questioned." He is apparently unaware of the results reported in the extensive postoperative studies published during the last few years. It has been definitely shown that splanchnicectomy does arrest the progress of the disease in many patients, and even more significant is the improvement, including alleviation of symptoms, maintained lowered blood pressure and improvement in cardiac and renal status shown in a high percentage of those operated on, even when the preoperative hypertensive changes were advanced. Although claims of cures have not been made by any surgeons, numerous cases have been carefully studied over postoperative periods up to twelve years with maintained normal blood pressures and restored cardiac and renal status. Contrary to the author's opinion, malignant hypertension is a distinct indication for splanchnicectomy, provided the cardiac and renal functions have not been irrevocably impaired. The other phases of treatment are well covered, although one may not agree that the nitrites are of any real value.

This little book, with the exception of treatment, fulfils its mission "as an introduction to hypertension" well. It really does more than this; it summarizes clearly and concisely the modern concept of the disease and in addition gives a well chosen bibliography. The latter should be of real value to any one interested enough to peruse further the literature on this highly important and still controversial disease. We recommend the work for general reading.

Modern Development of Chemotherapy. By E. Haringa, H. W. Julius, H. Veldstra and K. C. Winkler. Monographs on the Progress of Research in Holland During the War, No. 4. Paper. Price, $3.50. Pp. 175, with 31 illustrations. Elsevier Publishing Company, Inc., 215 Fourth Ave., New York 3, 1946.

This monograph is one in about twenty-four on the progress of research in the Netherlands during the war. Apparently the purpose of the series is to reveal the work undertaken by scientists in the Netherlands during the five years of German occupation. Such revelation is of course interesting to every one concerned with science. However, the monographs present more than historical interest; they contain much factual information, and the modern development of chemotherapy is no exception. For those who are interested in details, this monograph will be of value by making more complete their repository of data. The book is well written, is in English, is made up of good paper and contains a large number of illustrations and tables and extensive bibliographies at the end of each chapter. The contents include discussions on the mechanism of action of the sulfonamides and of para-aminobenzoic acid, divided into bacteriologic investigations, physicochemical investigations, chemical investigations and pharmacologic, immunologic and clinical investigations. There also is a brief discussion of a phase of mycotherapy concerned with Expansine, a derivative of Penicillium expansum. Unfortunately there is no index.

The Artificial Kidney. By Dr. W. J. Kolff, Internist of the Municipal Hospital "Engelenbergstichting," Kampen (Holland), with the cooperation of J. Van Noordwijk. Paper. Pp. 92, with illustrations. J. H. Kok N. V., Kampen, Holland, 1946.

This is a condensed English translation of the original Dutch by W. J. Kolff. The apparatus described as artificial kidney is essentially a vividialyzer. It is operated on the principle of dialysis and is proposed to be utilized for the removal of catabolic products from the blood of uremic patients. The earliest attempts to dialyze blood outside the body was made by Abel, Rowntree and Turner. After many endeavors the author, in cooperation with H. T. J. Berk, constructed an apparatus suitable for clinical use. A good dialyzer must be built on the principle of providing a spread of a small quantity of blood over a large surface; the blood must circulate in a closed system and the blood as well as the rinsing liquid must be maintained in continuous movement. The standard rinsing liquid used in their cases contains 0.6 per cent sodium chloride, 0.2 per cent sodium bicarbonate, 0.04 per cent potassium chloride and 1.5 to 3 per cent glucose. The concentration of the minerals potassium, sodium and chlorine and the alkali reserve is closely observed during dialysis. Kolff employed continuous dialysis in which the blood coming from the radial artery flowed only once through the apparatus and was then returned by way of the radial vein. This was sufficient to remove almost all the urea and other retention products from the blood. The largest quantity of urea removed in one dialysis amounted to 260 Gm. Other retention products removed are residual nitrogen, creatinine, uric acid, indoxyl, xanthoproteine and several chemotherapeutic substances.

The book contains a minute description of this artificial kidney apparatus with a full set of drawings, so that any good instrument maker should be able to construct the apparatus. Accurate instructions are also given for cleaning and sterilizing the apparatus. We are told that the Dutch edition contains a detailed account of the use of the artificial kidney in the treatment of the first 15 patients. Although 14 of the patients have died, the author feels that this cannot be held against the apparatus. It appears that the chances of recovery for these patients were so slight that recovery could hardly be expected. The 1 patient who was cured, he admits, probably would have recovered without the help of the apparatus. However, he insists that definite clinical improvement occurred in patients who appeared in an utterly hopeless condition and that death appeared to be postponed for a considerable time in spite of almost complete anuria.

Synopsis of Pathology. By W. A. D. Anderson, M.A., M.D., F.A.C.P., Professor of Pathology and Bacteriology, Marquette University School of Medicine, Milwaukee, Wisconsin. Fabrikoid. Second edition. Price, $6. Pp. 741, with 342 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1946.

In this edition Anderson continues to present pathology in a concise and compact form. Much of the book has been revised and greater emphasis given to tropical diseases, blast injuries, conditions important in military medicine and the nonbacterial infectious diseases. A discussion of epidemic hepatitis is now included. Although already beautifully illustrated, 78 new illustrations have been added. The references have been brought up to date. While these changes greatly enhance the usefulness of the book for reference or reorientation, they fail to correct its one serious though understandable fault, the superficiality of the first three basic chapters concerning inflammation, repair, regeneration, retrogressive changes and disturbances of circulation. Expansion of these chapters, which would not necessarily increase the size of the book if the unnecessarily large size of many of the illustrations was reduced, would greatly aid beginning medical and dental students and teachers of pathology. In the next edition it is hoped that the author will refrain from using the word pathology incorrectly as the synonym for the terms lesions or pathologic changes.

Modern Drug Encyclopedia and Therapeutic Index. Edited by Alexander B. Gutman, Ph.D., M.D., F.A.C.P., Assistant Professor of Medicine, College of Physicians and Surgeons, Columbia University, New York. Third edition. Fabrikoid. Price, $10. Pp. 1,157. Yorke Publishing Company, Inc., 49 W. 45th St., New York 19, 1946.

This book has become widely known as a reference source for information on the identity of proprietary articles. The third edition, like the preceding two editions, contains for each listed product a statement of composition, the name of the manufacturer, claims for actions and uses, dosage and how it is supplied. As a source of such information this book has real usefulness, but as a therapeutic guide its usefulness is definitely limited because even though the author has apparently attempted to omit "unreasonable claims" there are described many preparations with claims more reminiscent of advertising circulars than of the decisions of a critical therapeutic committee. The table of contents includes a foreword, a glossary, a list of pharmaceuticals, of biologic products and of allergens, a therapeutic index, manufacturers' and distributors' index and a general index.

Sex, Marriage and Family. By Thurman B. Rice, A.M., M.D., Professor of Bacteriology and Public Health, Indiana University School of Medicine, Indianapolis. Cloth. Price, $2.50. Pp. 272. J. B. Lippincott Company, 227 S. Sixth St., Philadelphia 5, 1946.

This book is the condensation of a long-continued interest in the problems revolving around men, women and sex. The author has studied the subject extensively and has talked with many persons of all ages and both sexes about problems in this field. His approach is realistic without the sacrifice of good taste. The book is a frank, complete, candid and idealistic discussion of marriage in the broad sense, dealing not only with sex but with economics, sociology and philosophy in their relation to the married state. He discusses at length the choice of a mate. He deals with wartime dislocations, war marriages and the return of soldiers from war, with the hazards to marriage which are a part of the aftermath of war. Any one who has the courage to face facts will find this book a refreshing source of information, advice and inspiration. All young people should read it before marriage rather than after.

Manual of Nursing Procedures, The Mount Sinai Hospital, New York City. Prepared by the Faculty of the Mount Sinai Hospital School of Nursing, Grace A. Warman, R.N., M.A., Principal. Editorial Committee: Blanche D. Gubersky, R.N., B.S., Bessie I. Wolfson, R.N., M.A., Felixa B. Sulesky, R.N., B.S., and Sylvia M. Barker, R.N. Loose-leaf. Fabrikoid. Price, $3. Pp. 313, with 31 illustrations. Mount Sinai Hospital Press, Fifth Ave. & 100th St., New York 29, 1946.

This compact volume designed to act as a handbook of nursing procedures for nurses in training at the Mount Sinai Hospital, New York, should admirably fulfil that function. It is well organized and well indexed, and the procedures are grouped according to a functional classification which makes reference to a particular procedure relatively easy. Twenty-one drawings give considerable assistance to the text in explaining such procedures as the disinfection of a stool or the setting up of a Wangensteen suction apparatus. Though the descriptions of the nursing procedures are brief, they appear to be adequate. General nursing procedures are covered under the headings of administrative routines, the central supply department, general nursing care, procedures for diagnostic tests and the administration of medicines. Special nursing procedures are included under the titles of medical procedures, procedures for the care of children, surgical procedures, procedures of the specialty services (including otology, ophthalmology, rhinolaryngology and neurology) and nursing care of the orthopedic patient. Operating room procedures and obstetric procedures have not been included in this volume, though a later volume on the former is in preparation. Among the newer procedures described are the intramuscular administration of penicillin, the management of the Wangensteen suction apparatus and the supervision of continuous intravenous infusions and of continuous bladder irrigation apparatus. Among the most valuable inclusions in the appendix are the tables of equivalents, abbreviations, symbols and synonyms.

To those interested in the development of the teaching functions of the nurse it is encouraging to find in Grace A. Warman's foreword the statement that "a knowledge of the patients' social conditions, methods of disease prevention, and the teaching elements of nursing which are included in the present day curriculum help the nurse to take her place in the community as a leader and teacher of health." It is even more encouraging to find the first statement under the method of procedure for treatment of pediculosis in children "Explain the procedure to the patient."

It is to be hoped that this manual will find a well deserved field of usefulness considerably beyond that of the Mount Sinai Hospital School of Nursing.

The Control of Venereal Disease. By R. A. Vonderlehr, M.D., Director, District No. 6, U. S. Public Health Service, and J. R. Heller Jr., M.D., Chief, Venereal Disease Division, U. S. Public Health Service. Foreword by Thomas Parran, M.D., Surgeon General, U. S. Public Health Service. Cloth. Price, $2.75. Pp. 240. Reynal & Hitchcock, 8 West 40th St., New York 18, 1946.

This book is by two doctors, one of whom has been and the other now is chief of the venereal disease division of the U. S. Public Health Service. Through cooperative relationships with state boards of health and secondarily with the larger local health units it has acquired perhaps the most extensive experience outside the armed forces with the venereal disease problem. Even in the armed services the venereal disease problem could be met only with the cooperation of the U. S. Public Health Service.

This book tells how the fight against venereal diseases was brought into the open by shattering the conspiracy of silence which rendered syphilis and gonorrhea unacceptable words on the radio and made discussion of these diseases taboo except in medical circles. The history of syphilis and its cause are discussed and so are the causes of gonorrhea and the so-called minor venereal diseases. A discussion of treatment is included under the title "Doctors Know How to Win." There are chapters on the use of penicillin, case finding, prostitution, rapid treatment, the relationship of venereal diseases to delinquency and vice versa, the influence of the war and present day control measures. Attention is given to a few typical cases indicating psychologic maladjustments as causes for sexual promiscuity and consequent venereal infections.

The book is written primarily for laymen and can be recommended to them for study. Physicians should read it primarily to familiarize themselves with the procedures advocated by public health authorities and the reasons for the recommendations. It is hardly likely that venereal diseases will be controlled by anything less than complete and well coordinated cooperation between doctors, health officials, sociologists, courts, police and the people at large. This book points the way to such cooperation.

Public Health Nursing in Syphilis and Gonorrhea. By Evangeline Hall Morris, Associate Professor of Nursing, Simmons College, Boston. Cloth. Price, $2.25. Pp. 239, with 18 illustrations. W. B. Saunders Company, W. Washington Square, Philadelphia, 1946.

A book written by a nurse for nurses to further education of nurses in venereal disease has long been needed. Miss Morris has produced that book. The first chapters are devoted to a presentation of the medical aspects of the venereal diseases. The chapter entitled "The Patient and His Needs" will be helpful in considering problems with which many patients are faced and will focus the attention of public health nurses on the patients' needs rather than on the disease alone. The suggested methods of epidemiology do not differ materially from what has already been proposed by many writers but bear repetition, since this phase of the venereal disease program is vital in bringing infectious venereal disease to medical attention. The section on clinic services points out the responsibilities of those staffing venereal disease clinics in making the clinic a desirable place for patients to come. Every nurse could profitably study the excerpts from interviews with two different patients. The inclusion of a chapter on family life education is pertinent, because nurses have many opportunities to guide parents, teachers and other groups in helping children toward attaining a wholesome concept of family life and character development. The author concludes the book with a discussion of the functions and preparation of public health nurses in venereal disease and points out opportunities for effective participation.

Toward Mental Health. By George Thorman. Public Affairs Pamphlet No. 120. Paper. Price, 10 cents. Pp. 32, with illustrations. Public Affairs Committee, Inc., 22 E. 38th St., New York 16, 1946.

This pamphlet is a condensed treatment of the mental hygiene problem in the United States during wartimes and after. It deals with fears, psychosomatic symptoms, war neuroses, moods, retreat from reality and such everyday manifestations of mental illness. It touches also on the organic psychoses and on behavior problems in children. It closes with a statement of the need for a national mental health program. It recognizes the National Committee for Mental Hygiene and the National Mental Health Foundation as organizations working toward better mental health. Like many of the Public Affairs pamphlets which deal factually with scientific and social problems and do not venture in the realm of political remedies for medicosocial illness, this is a useful publication which can be recommended by physicians to their patients interested in mental health problems.

The Challenge of Polio: The Crusade Against Infantile Paralysis. By Roland H. Berg. Introduction by Basil O'Connor, President, The National Foundation for Infantile Paralysis, Inc. Cloth. Price, $2.50. Pp. 208. The Dial Press, Inc., 461 Fourth Ave., New York 16, 1946.

This book is issued by the National Foundation for Infantile Paralysis, Inc., and deals, as its subtitle indicates, with the crusade against infantile paralysis. It is dedicated to the late president Franklin Delano Roosevelt, whose name has been so skilfully used to attract attention to the disease from which he suffered. The book is written for laymen with an introduction by Basil O'Connor, president of the National Foundation for Infantile Paralysis. It begins with a historical review of how poliomyelitis hit the headlines and it outlines Mr. Roosevelt's experiences. Research activities and the failure of various hopeful lines of investigation are reviewed. The alum spray fiasco is described. Experience with vaccines is reviewed, and the situation with respect to the Kenny technic and the associated controversy is reviewed. The book is a worth while historical document and a useful current review, particularly for those lay persons who are asked to work on behalf of the drive for polio foundations and for those who are requested to contribute.

The Popular Medical Encyclopedia: The Standard Guide on Health and Disease. By Morris Fishbein, M.D., Editor, Journal of the American Medical Association and Hygeia, the Health Magazine. Cloth. Price, $4.95. Pp. 540, with illustrations. Doubleday & Company, Inc., Garden City, New York, 1946.

This medical encyclopedia is exactly what its title indicates. It is a popular encyclopedia of medical terms from *abdomen* to *zyme*—the latter short for enzyme or ferment. The articles are short, clearly written and informative. It is not a health book or a textbook. It is exactly what its name indicates, that is, a popular encyclopedia. It should be useful in elementary and secondary schools as a student reference book and in teacher training colleges. It deserves a place in the library of the home where there is interest in matters pertaining to health and medicine.

Die interstitielle Nephritis. Von Privatdozent Dr. H. U. Zollinger, Prosektor am Pathologischen Institut der Universität Zürich. Mit einem Vorwort von Prof. Dr. H. v. Meyenburg. Paper. Price, 28 Swiss francs. Pp. 264, with 87 illustrations. New York & Basel: S. Karger, 1945.

The author's purpose is to review for the pathologist the changes which occur in renal interstitial tissue and to supplement this with personal observations and experiments. His thesis is that many of the interstitial reactions of the kidney are due to the deposition in renal lymphatics of abnormal proteins. The illustrations lack clarity. The specialist in renal pathology may find the volume useful for its bibliography. However, the value of a presentation so specialized that it neglects extrarenal pathologic conditions and only glances cursorily at the concurrent parenchymal changes is almost as scanty as its interest to the clinician.

Sex Problems of the Returned Veteran. By Howard Kitching, M.D. Foreword by Ernest R. Groves, Professor of Sociology, University of North Carolina, Chapel Hill, North Carolina. Cloth. Price, $1.50. Pp. 124 New York: Emerson Books, Inc., 1946.

This book is designed to give the veteran some insight into his problems of integration back into normal family life. It is published a year late to be of much help to the large majority of veterans. The general information contained on the subject of sex and marriage seem more applicable to the young and immature individual who is in need of premarital advice than to the returning veteran. The portion of the book dealing with anxiety as it is related to continence, masturbation and extramarital relationships will probably be the most helpful section to the returning veteran who is willing to wade through some of the rather obvious sociophilosophical discussion.

Estudio crítico del tratamiento médico de la insuficiencia cardíaca. Por Blas Moia, doctor en medicina, docente libre de patología médica de la Facultad de medicina de Buenos Aires. Paper. Pp. 107, with 16 illustrations. "El Ateneo," Florida 340, Cordoba 2099, Buenos Aires, 1945.

In this monograph Moia summarizes the indications for and the mode of action of the several forms of therapy in heart failure as he and others in Buenos Aires practice. Included is a brief description of the physiology of heart failure, the use of digitalis and the other regimens which may be employed, among which are diuretics, bleeding, cupping, purgatives, rest, sedatives and opiates, hypertonic glucose and oxygen. The cardiologist who wishes to be brought up to date on the point of view of the Argentine school will find this manuscript useful. It is well documented and has an extensive bibliography.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF *ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY.* ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INHERITANCE OF PROGRESSIVE MUSCULAR DYSTROPHY

***To the Editor:*—A woman aged 29 has three adult brothers with progressive muscular dystrophy and has lost one brother with the same disease. There is no history of this condition in her ancestry. She is seeking advice as to whether she would be liable to transmit this condition if she were to marry and have children.** **M.D., Ohio.**

ANSWER.—The absence of progressive muscular dystrophy in the immediate ancestry is not unusual, and many cases of this type have been reported in the medical literature. When the observations extend back into the third or fourth generation prior to the appearance of the disease, other cases are frequently disclosed. The appearance of the disease in a single generation is presumptive evidence that progressive muscular dystrophy is propagated by a sex-linked recessive factor. Transmission is effected usually by the females, who do not have clinical signs of the disease, to the males. It would be of value to know the type of progressive muscular dystrophy exhibited in the three brothers of this patient, as there is some variation in the ability to transmit the disease depending on the presenting syndrome.

The means of heredity in progressive muscular dystrophy is not fully known. In the ordinary case, the sex chromosome carrying the dystrophy factor is transmitted by the females of the family for a number of generations. In other instances there may be multiple recessive factors in which the number of factors necessary to induce the condition are fewer for males than for females. Attempts to elucidate the inheritance of muscular dystrophy illustrates the difficulties involved in the application of genetic principles to human problems. The disease probably is inherited in a number of ways. In some families there is transmission by a mendelian dominant; in others by a recessive factor.

The query cannot therefore be answered in a categoric manner. Without more complete knowledge of the appearance of the disease in previous generations, the type of inheritance is not clear. What evidence is available points to the disease in the males only, with probable transmission through the females. The patient would probably have affected male children and nonaffected female children, the females acting as carriers for succeeding generations.

HISTAMINE FOR ARTHRITIS

***To the Editor:*—Please discuss the use of histamine in rheumatic conditions.** **M.D., Mississippi.**

ANSWER.—Deutsch was the first to use histamine by iontophoresis for the treatment of arthritis. Most reports in the literature refer to the use of histamine by this method. Definite relief of pain and improvement in motion of joints has been observed. Similar clinical results have been reported following the use of histamine ointment, Imadyl (marketed by Hoffmann-LaRoche). According to reports in the literature this product contains 1 per cent of histamine and information supplied by the manufacturer indicates that it is in the form of the dihydrochloride. Apparently the good results which have been observed are due to the vasodilating effects of the drug.

In man histamine dilates the arterioles, venules and capillaries, irrespective of the manner of administration. It can be given slowly in a 1:250,000 dilution by the drip method and is a safe procedure. It may be used to alleviate acute attacks of allergic

POSSIBLE MASCULINIZING TUMOR

To the Editor:—A woman aged 22, a primipara, sixteen months post partum developed a husky, gruff, somewhat hoarse, male type of voice, about the third or fourth month of pregnancy. Competent study of the nose and throat fails to reveal any underlying cause. Complete physical examination does not show any male type secondary sex characteristics or any other abnormality. Please discuss the diagnosis and treatment.
M.D., New York.

ANSWER.—The main problem in a patient like this is whether or not there is a masculinizing tumor in either the adrenal cortex or an ovary. A careful search should be made for other masculinizing changes, such as growth of hair on the face, chest, abdomen, arms and legs, enlargement of the clitoris, decrease in the size of the breasts and long periods of amenorrhea. An abdominal and pelvic examination should be carried out. Often a tumor can be felt on physical examination alone. If a tumor is not felt, a flat plate should be made of the genitourinary tract. If this is negative, an intravenous pyelogram might be of some value in demonstrating a tumor of the adrenal cortex. It would also be of some value to determine the amount of 17-ketosteroids in the urine. In masculinizing tumors the concentration is usually greatly increased, sometimes tenfold. If all findings are negative and the only change is in the voice, the patient may be followed closely without resorting to surgical intervention. If, however, a definite tumor is found or if there are chemical changes in the urine that point to one, both the ovaries and adrenals should be explored surgically.

MISSED ABORTION

To the Editor:—Please discuss the following case: A woman aged 44, married, of Norwegian birth, with an entirely negative menstrual and other past history, had her last period which was normal, Feb. 22-27, 1946. Without other signs of pregnancy, small amounts of bright blood from the uterus appeared on April 29 and continued daily for one week. The patient was then hospitalized. All laboratory findings were negative except a positive Aschheim-Zondek test. The lower part of the abdomen was filled with a firm tumor of regular outline, evidently the uterus, with the consistency of a fibroid rather than a pregnancy. The clinical impression was early pregnancy and intramural fibroid, with impending spontaneous abortion. With bed rest the patient's general condition has remained unchanged but the tumor has steadily decreased to less than one third of its former size and has become softer. A negligible amout of blood has been lost in the past three weeks. At times a small amount of brownish material has been noted, which on one occasion had an offensive odor. There has been no bleeding or discharge for the past five days. The tumor apparently is still regressing in size. Roentgenograms do not reveal fetal parts.
M.D., Massachusetts.

ANSWER.—This is almost certainly a case of missed abortion. Another Aschheim-Zondek test should be performed and will almost certainly be negative unless there is still some living chorionic ectoderm in the uterus. Regardless of the result of the biologic test, a curettement should be performed to remove the remains of the pregnancy. It is possible that nature has already expelled the entire ovum or will soon do so. Therefore one may wait to see if the uterus will stop diminishing in size and normal menstruation will return. If the menses do not return in two months and a new gestation has not begun, and certainly if bleeding is profuse or irregular, a curettage should be done. X-ray films will rarely reveal fetal parts before four months of development, so the absence of fetal parts has no significance in this case.

CLINICAL PATHOLOGY

To the Editor:—What is the definition of "clinical pathology?" How and where did the term originate? Please give references.
Kano Ikeda, M.D., St. Paul.

ANSWER.—The constitution and by-laws of the American Society of Clinical Pathologists defines clinical pathology as "that branch of the science and practice of medicine which consists of the application of pathologic anatomy, physiology, chemistry, parasitology and bacteriology to the diagnosis of disease."

This comprehensive definition, adopted in 1934, expresses a growth which began centuries ago with the examination of urine and which blossomed out in the first half of the nineteenth century in the application of microscopy and chemistry to clinical medicine and in the second half of the same century in the application of bacteriology and more recently in the application of immunology.

The exact origin of the term "clinical pathology" is difficult to establish. One finds it as early as 1865 in the name of The Clinico-Pathological Society of Washington, D. C. Its proceedings were published in the *Journal of Medical Sciences* **55:**120-128, 412-418, 1868. These are clinical case reports with occasional necropsy findings and urinalyses.

W. Essex Wynter and Frank J. Wethered are the authors of "A Manual of Clinical and Practical Pathology" published in 1890 by Blakiston. The introduction is of historical interest. It states as the object of the book "to embrace . . . a description of various methods which may be employed in the investigation of morbid changes both before and after death. For the most part chemistry, pathology and clinical medicine have hitherto been studied separately, whereas in many of their aspects they are so mutually involved that it is absolutely necessary to consider them together."

Clinical pathology appears as a subheading of pathology for the first time in 1905 in volume XII of the second series of the Index Catalogue of the Library of the Surgeon General's Office. There one finds on page 666 a series of papers published between 1904 and 1907.

LUPUS ERYTHEMATOSUS

To the Editor:—What is the latest treatment of lupus erythematosus? Allergy has been reported as a possible cause of lupus erythematosus. Is Benadryl of any value as reported by a "lay" publication?
E. J. Wintenburg, M.D., Van Nuys, Calif.

ANSWER.—There is no valid reason for the belief expressed recently by Teilum (*Acta med. Scandinav.* **123:**126, 1946) that disseminated lupus erythematosus is related to allergy. Unlike periarteritis nodosa, lupus erythematosus is not associated with a clinical history or manifestations of allergy such as urticaria, eczema, asthma or eosinophilia. It is true that the fibrinoid degeneration of connective tissue characteristic of advanced lupus erythematosus, which is responsible for the changes in the walls of small blood vessels and in serous membranes, is also seen in allergic diseases and can be reproduced in experimental animals by the injection of bacterial and other foreign proteins (Rich, A. R., and Gregory, J. E.: *Bull. Johns Hopkins Hosp.* **72:**65 [Feb.], **73:**239 [Oct.] 1943). But this connective tissue change is not specific for allergy, for it can be found in a variety of nonallergic conditions associated with connective tissue injury—around foreign bodies, in the base of a peptic ulcer, in diffuse scleroderma, in chronic infections.

Benadryl has been used in the treatment of lupus erythematosus but has not been found to be of value. There is as yet no specific therapy for the disease. The patient's nutrition should be improved by a well balanced diet, high in calories and reinforced with supplementary vitamins. Protection against bright light sometimes seems to be of value. Intercurrent infections should be promptly controlled with the appropriate antibiotic. In a few instances remissions have been associated with the administration of testosterone propionate or with castration, but the causal relationship is not convincing. This form of therapy has been based entirely on the fact that 95 per cent of the cases of disseminated lupus erythematosus occur in females.

DIET AND MEDICATION AFTER CHOLECYSTECTOMY

To the Editor:—Please discuss diet and medication following cholecystectomy.
M.D., New York.

ANSWER.—A special diet is not usually required by patients following a cholecystectomy. While the storage function of the gallbladder is lost, no disturbance in the absorption and digestion of fat or other foodstuffs results from this fact. For a time at least following the operation there occurs a more or less continuous flow of bile into the duodenum. In the normal person the bile secreted in the intervals between meals is stored in the gallbladder, where it undergoes concentration. Evacuation of the gallbladder occurs when food from the stomach enters the duodenum. Theoretically this should make for the better digestion and absorption of fat in the intestine. The factor of safety is so great, however, that no discoverable disturbance in digestion occurs when the flow of bile into the intestine is continuous rather than intermittent. As time goes on the common bile duct becomes dilated following cholecystectomy and an intermittent flow of bile into the intestine becomes partially reestablished.

Queries and Minor Notes

HISTAMINE FOR ARTHRITIS

To the Editor:—Please discuss the use of histamine in rheumatic conditions.

M.D., Mississippi.

ANSWER.—Deutsch was the first to use histamine by iontophoresis for the treatment of arthritis. Most reports in the literature refer to the use of histamine by this method. Definite relief of pain and improvement in motion of joints has been observed. Similar clinical results have been reported following the use of histamine ointment, Imadyl (marketed by Hoffmann-LaRoche). According to reports in the literature this product contains 1 per cent of histamine and information supplied by the manufacturer indicates that it is in the form of the dihydrochloride. Apparently the good results which have been observed are due to the vasodilating effects of the drug.

In man histamine dilates the arterioles, venules and capillaries, irrespective of the manner of administration. It can be given slowly in a 1:250,000 dilution by the drip method and is a safe procedure. It may be used to alleviate acute attacks of allergic or palindromic arthritis. Its value in the treatment of rheumatic conditions is not definitely established, although it does seem to give symptomatic relief in many subjects. More work is necessary before definite conclusions can be drawn regarding its therapeutic value.

INFECTIOUS RELAPSE AFTER PENICILLIN TREATMENT OF RECENTLY ACQUIRED SYPHILIS

To the Editor:—A man received antisyphilitic treatment with penicillin while in the army in May 1945. In March 1946 he transmitted the disease to his wife. He denies the possibility of reinfection. Have cases of infectious relapse been reported after penicillin treatment of recently acquired syphilis?

F. C. Katzenstein, M.D., Salem, Ill.

ANSWER.—Infectious relapse is a finding of all investigators studying the penicillin therapy of syphilis when the drug employed in the treatment of a recently acquired infection is insufficient to arrest the disease. Using total dosages of 1.2 million Oxford units of sodium penicillin, the amount of drug employed in most published material to date, the incidence of infectious relapse reported by various authors is from 1 to 5 per cent. Actually more recent experience has indicated that it is probably considerably in excess of these figures.

The first detectable relapsing lesion will usually occur from four to six months after therapy has been completed, though lesions are known to have resulted within the first month and after more than one year. Whenever treatment fails to cure freshly acquired syphilis, infectious relapse and transmission of the disease under favorable circumstances are accordingly a possibility. Pillsbury's report from the European theater of operation (*Am. J. Syph., Gonor. & Ven. Dis.* **30:**134 [March] 1946) indicates that soldiers treated there with penicillin for syphilis yielded a known incidence of infectious relapse of 1 to 2 per cent, and statistical data are given on 72 such cases. There is a distinct possibility that soldiers under such circumstances returning to civilian life will infect their marital partner unless medical supervision continues to be adequate during the transition period from military to civilian life.

Failure of serologic response or serologic relapse is often a premonitory sign of impending infectious relapse and warns of the development of clinically demonstrable lesions containing Treponema pallidum. Thus, most patients who fail to respond to penicillin therapy will maintain a high serologic titer for syphilis when a quantitative test is employed or will show an increasing titer following the initial reduction. The test will at times, of course, become completely negative only to revert to positive when infectious lesions develop, or shortly before.

Medical follow-up of all penicillin treated cases of early syphilis should consist of a blood serologic test and physical inspection for skin and mucous membrane lesions on approximately a monthly basis for at least the period during which relapse is likely to occur. That would be, according to our present knowledge, for a minimum of ten to twelve months after the completion of therapy. Among the most important facts which determine the possibility of relapse are total dosage of penicillin employed and the duration of the disease when treatment is commenced. Thus in the initial publications of penicillin therapy of early syphilis (J. E. Moore and others, THE JOURNAL, Sept. 9, 1944, p. 67) the percentage of serologic and clinical relapse combined was 3.2 for seronegative primary, 5 for seropositive primary and 10 for early secondary syphilis. This same study mentions 31 cases of clinical relapse in early syphilis following penicillin therapy. Small dosage of penicillin is particularly prone to result in infectious relapsing syphilis, as is shown in the experimental study by G. W. Binkley and his associates (Rapid Treatment of Early Syphilis with Small Doses of Penicillin, *Arch. Dermat. & Syph.* **51:**200 [March] 1945) and in the increasing number of reports of development of infectious syphilis following the use of penicillin to treat some other disease, in particular gonorrhea (Atcheson, D. W.: Secondary Syphilis Following Penicillin Therapy of Gonorrhea, *Am. J. Syph., Gonor. & Ven. Dis.* **29**:423 [July] 1945. Walker, A. E., and Barton R. L.: The Treatment of Gonorrhea with Penicillin During the Incubation Period of Early Phase of Syphilis, *Ven. Dis. Inform.* **26**:241 [Nov.] 1945. Leifer, William, and Martin, S. P.: Penicillin in Early Syphilis, The Journal, Jan. 26, 1946, p. 202. Fromer, S.; Cutler, J. C., and Levitan, S.: Masking Early Syphilis by *Penicillin Treatment of Gonorrhea, Ven. Dis. Inform.* **27**:174 [July] 1946).

POSSIBLE MASCULINIZING TUMOR

To the Editor:—A woman aged 22, a primipara, sixteen months post partum developed a husky, gruff, somewhat hoarse, male type of voice, about the third or fourth month of pregnancy. Competent study of the nose and throat fails to reveal any underlying cause. Complete physical examination does not show any male type secondary sex characteristics or any other abnormality. Please discuss the diagnosis and treatment.

M.D., New York.

Answer.—The main problem in a patient like this is whether or not there is a masculinizing tumor in either the adrenal cortex or an ovary. A careful search should be made for other masculinizing changes, such as growth of hair on the face, chest, abdomen, arms and legs, enlargement of the clitoris, decrease in the size of the breasts and long periods of amenorrhea. An abdominal and pelvic examination should be carried out. Often a tumor can be felt on physical examination alone. If a tumor is not felt, a flat plate should be made of the genitourinary tract. If this is negative, an intravenous pyelogram might be of some value in demonstrating a tumor of the adrenal cortex. It would also be of some value to determine the amount of 17-ketosteroids in the urine. In masculinizing tumors the concentration is usually greatly increased, sometimes tenfold. If all findings are negative and the only change is in the voice, the patient may be followed closely without resorting to surgical intervention. If, however, a definite tumor is found or if there are chemical changes in the urine that point to one, both the ovaries and adrenals should be explored surgically.

MISSED ABORTION

To the Editor:—Please discuss the following case: A woman aged 44, married, of Norwegian birth, with an entirely negative menstrual and other past history, had her last period which was normal, Feb. 22-27, 1946. Without other signs of pregnancy, small amounts of bright blood from the uterus appeared on April 29 and continued daily for one week. The patient was then hospitalized. All laboratory findings were negative except a positive Aschheim-Zondek test. The lower part of the abdomen was filled with a firm tumor of regular outline, evidently the uterus, with the consistency of a fibroid rather than a pregnancy. The clinical impression was early pregnancy and intramural fibroid, with impending spontaneous abortion. With bed rest the patient's general condition has remained unchanged but the tumor has steadily decreased to less than one third of its former size and has become softer. A negligible amout of blood has been lost in the past three weeks. At times a small amount of brownish material has been noted, which on one occasion had an offensive odor. There has been no bleeding or discharge for the past five days. The tumor apparently is still regressing in size. Roentgenograms do not reveal fetal parts.

M.D., Massachusetts.

Answer.—This is almost certainly a case of missed abortion. Another Aschheim-Zondek test should be performed and will almost certainly be negative unless there is still some living chorionic ectoderm in the uterus. Regardless of the result of the biologic test, a curettement should be performed to remove the remains of the pregnancy. It is possible that nature has already expelled the entire ovum or will soon do so. Therefore one may wait to see if the uterus will stop diminishing in size and normal menstruation will return. If the menses do not return in two months and a new gestation has not begun, and certainly if bleeding is profuse or irregular, a curettage should be done. X-ray films will rarely reveal fetal parts before four months of development, so the absence of fetal parts has no significance in this case.

CLINICAL PATHOLOGY

To the Editor:—What is the definition of "clinical pathology?" How and where did the term originate? Please give references.

Kano Ikeda, M.D., St. Paul.

Answer.—The constitution and by-laws of the American Society of Clinical Pathologists defines clinical pathology as "that branch of the science and practice of medicine which consists of the application of pathologic anatomy, physiology, chemistry, parasitology and bacteriology to the diagnosis of disease."

This comprehensive definition, adopted in 1934, expresses a growth which began centuries ago with the examination of urine and which blossomed out in the first half of the nineteenth century in the application of microscopy and chemistry to clinical medicine and in the second half of the same century in the application of bacteriology and more recently in the application of immunology.

The exact origin of the term "clinical pathology" is difficult to establish. One finds it as early as 1865 in the name of The Clinico-Pathological Society of Washington, D. C. Its proceedings were published in the *Journal of Medical Sciences* **55**: 120-128, 412-418, 1868. These are clinical case reports with occasional necropsy findings and urinalyses.

W. Essex Wynter and Frank J. Wethered are the authors of "A Manual of Clinical and Practical Pathology" published in 1890 by Blakiston. The introduction is of historical interest. It states as the object of the book "to embrace . . . a description of various methods which may be employed in the investigation of morbid changes both before and after death. For the most part chemistry, pathology and clinical medicine have hitherto been studied separately, whereas in many of their aspects they are so mutually involved that it is absolutely necessary to consider them together."

Clinical pathology appears as a subheading of pathology for the first time in 1905 in volume XII of the second series of the Index Catalogue of the Library of the Surgeon General's Office. There one finds on page 666 a series of papers published between 1904 and 1907.

LUPUS ERYTHEMATOSUS

To the Editor:—What is the latest treatment of lupus erythematosus? Allergy has been reported as a possible cause of lupus erythematosus. Is Benadryl of any value as reported by a "lay" publication?

E. J. Wintenburg, M.D., Van Nuys, Calif.

Answer.—There is no valid reason for the belief expressed recently by Teilum (*Acta med. Scandinav.* **123**:126, 1946) that disseminated lupus erythematosus is related to allergy. Unlike periarteritis nodosa, lupus erythematosus is not associated with a clinical history or manifestations of allergy such as urticaria, eczema, asthma or eosinophilia. It is true that the fibrinoid degeneration of connective tissue characteristic of advanced lupus erythematosus, which is responsible for the changes in the walls of small blood vessels and in serous membranes, is also seen in allergic diseases and can be reproduced in experimental animals by the injection of bacterial and other foreign proteins (Rich, A. R., and Gregory, J. E.: *Bull. Johns Hopkins Hosp.* **72**:65 [Feb.], **73**:239 [Oct.] 1943). But this connective tissue change is not specific for allergy, for it can be found in a variety of nonallergic conditions associated with connective tissue injury—around foreign bodies, in the base of a peptic ulcer, in diffuse scleroderma, in chronic infections.

Benadryl has been used in the treatment of lupus erythematosus but has not been found to be of value. There is as yet no specific therapy for the disease. The patient's nutrition should be improved by a well balanced diet, high in calories and reinforced with supplementary vitamins. Protection against bright light sometimes seems to be of value. Intercurrent infections should be promptly controlled with the appropriate antibiotic. In a few instances remissions have been associated with the administration of testosterone propionate or with castration, but the causal relationship is not convincing. This form of therapy has been based entirely on the fact that 95 per cent of the cases of disseminated lupus erythematosus occur in females.

DIET AND MEDICATION AFTER CHOLECYSTECTOMY

To the Editor:—Please discuss diet and medication following cholecystectomy.

M.D., New York.

Answer.—A special diet is not usually required by patients following a cholecystectomy. While the storage function of the gallbladder is lost, no disturbance in the absorption and digestion of fat or other foodstuffs results from this fact. For a time at least following the operation there occurs a more or less continuous flow of bile into the duodenum. In the normal person the bile secreted in the intervals between meals is stored in the gallbladder, where it undergoes concentration. Evacuation of the gallbladder occurs when food from the stomach enters the duodenum. Theoretically this should make for the better digestion and absorption of fat in the intestine. The factor of safety is so great, however, that no discoverable disturbance in digestion occurs when the flow of bile into the intestine is continuous rather than intermittent. As time goes on the common bile duct becomes dilated following cholecystectomy and an intermittent flow of bile into the intestine becomes partially reestablished.

USE OF FLUIDS IN CRANIOCEREBRAL INJURIES

To the Editor —Since the surplus army and navy dried plasma became freely available for civilian medical practice in abundant supply, I have noted many instances in which this plasma is being used for patients with fractured skulls without outward signs of shock and not being prepared for any immediate operative procedure Apparently the rationale of this therapy is to prevent shock and to maintain the osmotic pressure of the blood and possibly reduce intracranial pressure The plasma is being given in fairly large amounts, varying from 250 to 1,000 cc, reconstituted to its original volume The question arises as to whether the use of these large amounts of isotonic plasma may not be more harmful than beneficial, because of the possibility of the increased blood volume causing an increase in intracanial pressure. I would appreciate a discussion of the use of intravenous fluids in the presence of a fractured skull, with particular emphasis on the use of hypertonic preparations such as concentrated albumin, glucose or magnesium sulfate preparations

M D, New York

Answer —There are few subjects in medicine that have been characterized by as much loose thinking, talking, writing and practice as has the use of fluids in cases of craniocerebral injury In this connection there are certain facts which must not be lost sight of First and foremost, the victims of craniocerebral injuries are as much in need of fluids and a proper fluid, electrolyte and protein balance as is any other type of patient Second, it is impossible to dehydrate the brain without at the same time dehydrating the patient as a whole Third, cerebral edema plays *only a relatively small role in the picture of craniocerebral injury* Dehydration and the use of hypertonic solutions of any kind have little place in the treatment of such injuries Without doubt the use of such solutions and dehydration has resulted in far more damage than they have good Certainly one can produce shrinkage of the brain by the use of hypertonic solutions intravenously, but, unless a serious state of dehydration is maintained thereafter, the shrinkage of the brain will not persist The use of hypertonic solutions in cases of craniocerebral injury should be limited to those relatively few instances in which it becomes necessary to reduce intracranial tension temporarily while preparing to provide more permanent relief surgically

It is now generally recognized that the only adequate treatment for shock is whole blood given intravenously promptly and in sufficiently large quantities to supply the patient's needs whatever they may be Plasma and serum are not satisfactory substitutes for whole blood Their use in such circumstances is excusable only until whole blood can be secured. On the other hand, plasma may be preferable when one seeks to repair a protein deficiency This would rarely be desirable for a patient with a recent craniocerebral injury The use of 250 to 1,000 cc of fluid, be it plasma or other isotonic fluid, would rarely be harmful to a patient with such an injury In fact it frequently would be desirable as a means of insuring that the patient had adequate fluids However, as noted previously, there would only rarely be instances in which plasma would be the fluid of choice

PAINFUL UTERINE CONTRACTIONS DURING PREGNANCY

To the Editor —A secundipara, tertigravida, complains of contractions of the uterus which are not painful but have been troublesome during the last four and one-half months of the pregnancy When they occur they temporarily incapacitate her and they become more frequent and severe as the pregnancy progresses The first labor was associated at its onset with spontaneous rupture of the membranes just before term but was otherwise normal During the second pregnancy contractions began at four and one half months, and various antispasmodics and sedatives were used, with negligible results Labor was one month premature, with spontaneous rupture of the membranes four days prior to delivery. The contractions during the last two months of that second pregnancy were so severe as to incapacitate her for even the lightest tasks. Is this condition physiologic? Should continued sedation be used or is there any specific preparation for the condition? Louis H. Bos, M D, Chicago

POSSIBLE TOXICITY OF PHENYL-MERCURIC BORATE USED AS PRESERVATIVE FOR PLASMA

To the Editor —What is the toxicity of phenyl-mercuric borate used as a preservative for dried plasma? Is there any danger if plasma containing it is administered in large quantities (5 to 10 units of 250 cc. each within a period of twenty-four to forty-eight hours) to patients with such illnesses as burns covering a large surface of the body area? This plasma contains sufficient phenyl-mercuric borate to constitute a 1:50,000 dilution when the plasma is restored for use

M D, New York

Answer —Phenyl-mercuric borate combines with plasma proteins so that its toxicity is changed and probably lowered When a patient receives large doses of plasma containing a 1:50,000 dilution of phenyl-mercuric borate, for instance 10 units of 250 cc each, he receives 50 mg. of phenyl-mercuric borate With such an amount, especially in the case of burns with already damaged kidneys, the possibility of toxic action cannot be overlooked

It is not necessary to add preservatives to plasma to preserve in the dried or frozen state. With ordinary precautions the stability can be safely maintained without the addition of preservatives. When large doses of plasma are used (over 2,000 cc in twenty-four hours), preference should be given to plasma containing no preservatives For smaller doses such precaution *is not needed*

PREMENSTRUAL BLEEDING

To the Editor.—A common complaint in my practice is a brownish vaginal discharge for from three to nine days prior to the onset of the menses Most of the patients are young, healthy and apparently normal women Please discuss this problem and the treatment indicated

M D, Michigan

Answer —The brown discharge is mild premenstrual bleeding and is not uncommon It is usually due to the hyperemia which is present in all the pelvic organs, but in most instances an abnormality of the cervix will be found such as so-called erosions or polyps Hence in all cases of premenstrual brown or bloody discharge a complete pelvic examination should be made, including the use of a vaginal speculum Removal of cervical polyps and cauterization of erosions will cure most of the cases

TREATMENT OF CEREBRAL HEMORRHAGE

To the Editor —Prior to my entering the service I had a patient who developed a paralysis of the vocal cords and the entire right side of his body after a cerebral hemorrhage On my return he is still unable to talk but can use his leg and arm to some extent. His son, who is still in the service, feels that something can be done for his father in the way of brain surgery. Is there any one in this country who could relieve this man by surgery?

M D, Iowa

Answer —It would be impossible to give a satisfactory answer to this query without having available a detailed history of the development and course of the patient's disability and the results of a careful neurologic and general physical examination, plus such laboratory data as might then appear indicated If the original diagnosis of "cerebral hemorrhage" is correct, or if the patient suffers some other type of cerebrovascular disorder such as a cerebral thrombosis, there is nothing that neurologic surgery would have to offer. There are numerous competent neurologic surgeons throughout the United States to whom this patient could be referred for an examination and an opinion as to the possibilities of surgical treatment. Those who have been certified are so indicated in the American Medical Directory or are listed in the Directory of Medical Specialists

CHEMOTHERAPY IN THE MANAGEMENT OF WOUNDS

CHAMP LYONS, M D.
New Orleans

It is important to emphasize the limited role of chemotherapy in the management of wounds.[1] The basic tenet of the current philosophy in this regard is sound surgical care.[2] Blood transfusion and chemotherapy are important features of a supportive program designed to expedite the surgical treatment of the wounded. Of all the measures devised to prevent infection, only active immunization with tetanus toxoid may be said to have achieved its purpose completely. The only other prophylactic procedure of comparable value is initial surgical management of the wound. The greatest usefulness of antibacterial drugs has been in the therapy of impending or established infection complicating the surgical management of the wound.

One of the more important recent advances in the management of wounds is a renewed appreciation of the clinical distinction between invasive infection and localized suppuration of the wound.[3] With the help of the bacteriologist it has been established that invasive infection demands the presence of hemolytic streptococci, staphylococci or toxigenic clostridiums. However, the presence of such potentially invasive pathogens cannot be correlated constantly or even frequently with clinical signs of invasive infection. The predominant clinical pattern of infection may be suppuration of the wound even when bacteriologic cultures demonstrate the presence of potentially invasive bacteria. Suppuration of a wound may also occur in the absence of invasive pathogens. In such instances, the predominant bacteria are proteolytic against substrates of animal protein and have been classified as wound pathogens.[4] The clinical pattern of invasive infection indicates the presence of true pathogens, but suppuration of a wound may be due to true pathogens, wound pathogens or a combination of the two groups.

The combined experience of World Wars I and II has shown that the cleanly excised wound of soft parts develops invasive infection due solely to hemolytic streptococci[5] Incompletely excised wounds of soft parts and wounds complicated by fracture are vulnerable to invasive infection by any of the true pathogens. On the basis of the frequently demonstrated hazard of contamination it seems fair to conclude that the character of the wound is more important than the presence of the bacteria The distinguishing feature of wounds vulnerable to staphylococcic and clostridial infection is the presence of devitalized tissue or blood clot The presence of a pabulum of wound protein nutritionally acceptable to the bacteria becomes an important contributing factor in invasive infections of wounds due to staphylococci or toxigenic clostridiums.

This "pabulum theory" is of even greater importance in the causation of suppuration of the wound.[6] By definition, the virulence of wound pathogens is restricted to the proteolysis of devitalized tissue protein. The prompt control of infection due to Pseudomonas aeruginosa through the arrest of exudation by the secondary suture or skin grafting of a surface wound[7] would seem adequate refutation of the "germ theory" of suppuration of the wound

Experience with the management of chronically infected wounds has shown that the persistence of devi-

talized tissue or sequestrums prevents chemotherapeutic sterilization of the wound.[8] All except the most sensitive organisms are resistant even to high local concentrations of antibacterial agents in suppurative wounds. The local trauma incident to topical therapy increases the exudate from the wound and favors the growth of wound pathogens resistant to the agent employed.[9]

Rustigian has demonstrated that among the wound pathogens there are many organisms naturally resistant to antibacterial agents.[10] The most important of these is the ubiquitous Clostridium sporogenes which is resistant to sulfonamide compounds, penicillin and streptomycin. The important aerobic gram-negative wound pathogens are resistant to sulfonamide compounds in exudates from the wound, are insensitive to penicillin and inherit or readily acquire a resistance to streptomycin. Clinical experience with established infection has shown that the sulfonamide compounds are extremely effective against hemolytic streptococci, have a limited usefulness against staphylococcic infections and are relatively ineffective against gas gangrene. Streptomycin is ineffective against the clostridiums. With the exception of individually resistant strains, penicillin is effective against all the potentially invasive pathogens.

Sulfonamide therapy has been shown to be adequate for the wound endangered only by hemolytic streptococci. Penicillin is the drug of choice for all other wounds subject to invasive infection. No virtue is attached to combinations of penicillin and a sulfonamide compound in the treatment of infected wounds,[11] probably because of the presence of a sulfonamide inhibitor in exudates from wounds. This is contrary to experience in the management of infections of the urine, bile and spinal fluid wherein the antagonist of the drug is diluted or absent.

The only immediately effective treatment for suppuration of a wound is precise surgical toilet of the wound. Chemical and bacterial methods of débridement are more slowly and less certainly effective. After surgical removal of the obvious pabulum of wound protein, further bleeding and serous effusion should be prevented by the use of splints, pressure dressings and delayed or primary closure of the wound.

COMMENT

There is now considerable agreement that the major usefulness of chemotherapy is for the treatment of impending or established invasive infection during the initial, reparative and reconstructive phases of the surgical management of a wound. This is most certainly and expeditiously accomplished by the systemic administration of the selected drug.

Suppuration of a wound is believed to be due more to the presence of a pabulum of wound protein than to any specific bacterial virulence. No available antibacterial agent can completely sterilize an open wound. Topical, or local, chemotherapy has been discarded as ineffective and deleterious.[12] Suppuration of a wound is an indication for repeated surgical toilet of the wound.

Closure, not sterilization, of the wound is the practical objective of the early phases of management. Efforts to abolish infection are necessarily integrated with efforts to expedite the healing of the wound. The most important accessory procedures in this regard are the correction of anemia and the restoration of tissue protein deficits. The known depressant effects of sulfonamide compounds on hematopoiesis, the intestinal synthesis of essential metabolites and the appetite in general are further reasons to establish penicillin as the chemotherapeutic agent of choice in the management of wounds.

CONCLUSIONS

1. The prophylaxis of infected wounds is accomplished by active immunization with tetanus toxoid and initial surgical management.
2. Chemotherapy by the systemic route is indicated for the treatment of impending or established invasive infection complicating the surgical management of the wound.
3. Suppuration of the wound is an indication for surgical procedure.
4. Local chemotherapy is unnecessary and undesirable.
5. Penicillin by the systemic route is the chemotherapeutic agent of choice to supplement an aggressive surgical program of the management of wounds.

WOUND SHOCK

DR. JOHN D. STEWART
Buffalo

The clinical picture which is characteristic of traumatic shock may result from a variety of causes acting singly or in combination. Propulsive failure or cardiac deficiency, such as is seen in coronary thrombosis or severe arrythmias; mechanical interference with venous return and cardiac filling, as in strangulation of intestinal loops, cardiac tamponade or pulmonary embolism; dilatation of the vascular bed, as in peritonitis or overwhelming invasive infections, and oligemia due to dehydration, hemorrhage or burns, all are conditions which, though different in their nature and treatment, nevertheless may be responsible for reduction in cardiac output, hypotension and tissue anoxia. If the primary cause goes unrelieved the state of shock tends to progress to a point of irreversibility in which treatment will not save life. In any case of shock, therefore, it is of urgent importance to identify and treat the primary cause as well as the resultant physiologic disturbances.

In a theoretic analysis of the causes of shock in battle casualties one has to consider such varied factors as hemorrhage, sepsis, dehydration, burns and loss of plasma, absorption of toxins from damaged tissues, contamination of body cavities and serous effusions, sectioning of the cord or major neural trunks, pulmonary fat embolism, pulmonary thromboembolism, pulmonary blast injury and pulmonary edema and direct interference with cardiac output by mediastinal trauma. Furthermore, pain, emotional tension, exposure to cold and dampness and malnutrition may constitute active contributory influences. Any of these circumstances may be important determinants in the shock seen in the forward battle zones. However, there is considerable evidence to indicate that loss of blood dominates the early picture in the majority of severe wounds inflicted by penetrating high explosive missiles. This evidence is significant not only in the proper management of battle casualties but in relation to the mechanism of traumatic shock and its treatment in civilian surgical practice.

"Sulfonamide Therapy.—1. The general policies regarding the local use of chemotherapeutic agents have been enunciated in paragraph 21, WD Technical Bulletin Medical 147 (TB Med 147), March 1945. . . . Experience in wound management justifies the abandonment of local use of any chemical agent in a wound for its supposed antiseptic effect in the prevention or treatment of infection.

"2. The practice of routine local application of crystalline sulfonamides to wounds as an emergency aid measure and prior to initial wound surgery will be discontinued. The local application of this agent to wounds not involving serous cavities following wound surgery will also be discontinued and its local use in wounds involving serous cavities is not recommended."

Read in the symposium on "Wound Management" before the Section on Surgery, General and Abdominal, at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

TABLE 1.—*Blood Volume Data on Severely Wounded Soldiers*

Restorative therapy and surgical intervention have taken place between initial determinations of blood volume and secondary determinations twenty-four hours later.

	Therapy Before Study		Initial Blood Volume, Percentage of Normal	Therapy First 24 Hrs.		Blood Volume, Percentage of Normal
	Plasma, Cc.	Blood, Cc.		Plasma, Cc.	Blood, Cc.	
Average........	490	120	79.9	950	1,310	94.9
High............	1,250	2,500	123.0	3,000	4,000	135.2
Low............	0	0	28.1	0	0	59.8
Number of observations...	76	76	75	67	67	47

A group of gravely wounded, nontransportable casualties were examined in forward field hospitals a few miles behind the battle line. All were in actual or imminent shock on admission. Compound fractures, traumatic amputations and penetrating abdominal and thoracic wounds predominated in the 100 cases studied. In the majority of cases the wounds were multiple. The average interval between wounding and admission to the shock ward of the field hospital was 4.9 hours, the maximum was 25.2 hours. Plasma volume, plasma protein concentration and the red cell hematocrit reading were determined immediately after admission and again twenty-four hours later, after the patient had received restorative therapy and had been operated on. Further determinations were made subsequently during convalescence. Seventeen of the 100 patients died under observation without recovering sufficiently to be evacuated to the rear. The amounts of blood and plasma administered were recorded. From the patient's weight his theoretic normal blood volume was computed, by the use of standard normal values obtained from the study of normal soldiers. Assumptions are involved in such calculations which render the data tentative and suggestive in value rather than decisive and final. The biochemical methods used have been previously described.[1]

TABLE 2.—*Average Values in Percentage of Normal for Plasma Protein Concentration, Hematocrit, Plasma Volume and Blood Volume at Varying Intervals After Severe Wounding in Eighty-seven Patients*

Interval After Wounding, Days	Plasma Protein Concentration, Percentage of Normal		Hematocrit, Percentage of Normal		Plasma Volume, Percentage of Normal		Blood Volume, Percentage of Normal	
	Average	No. of Observations	Average	No. of Observations	Average	No. of Observations	Average	No. of Observations
Initial	82.5	71	86.6	86	89.6	84	81.3	84
1 to 4	90.0	114	79.6	102	105.5	44	91.3	44
5 to 8	90.3	50	77.6	50	100.0	7	85.4	7
9 to 12	91.6	33	83.7	33	105.8	12	94.1	12
13+	93.6	9	91.8	22	103.4	7	97.3	7

From the data shown in table 1 reduction in the blood volume of the patients is found to be the rule just after admission. Despite the fact that the average patient had received a pint of plasma and a small amount of blood, his blood volume was under 80 per cent of normal. Twenty-four hours later, by which time 950 cc. of plasma and 1,310 cc. of blood had been administered, the average blood volume had risen to 95 per cent. Considerable variation is evident, and in some instances the initial blood volume appeared to be normal. Furthermore in some cases oligemia was still present at the end of twenty-four hours despite replacement therapy. Presumably further loss of blood took place in such cases before, during or after surgical intervention. With respect to dosage of blood and plasma, the figures suggest that in an occasional case the oligemia was overcorrected. Undercorrection was much more common, however. This is brought out by considering the average value for blood volume at the end of twenty-four hours. Not only was the average still 5 per cent below normal, but there was an associated reduction in the hematocrit reading and in the plasma protein concentration. If these data are valid one must infer that the average soldier receiving a serious shock-producing wound must be given at least 2,000 cc. of blood if the volume of blood is to be restored to approximately normal at the end of twenty-four hours. This presupposes that further blood or plasma loss of consequence does not occur during treatment. Studies made on these patients later show that the quantity of blood required to repair the immediate oligemia of shock is insufficient to maintain normal hemoglobin and plasma protein values during the early period of the repair of the wound and convalescence. This point is brought out in chart 1 and table 2.

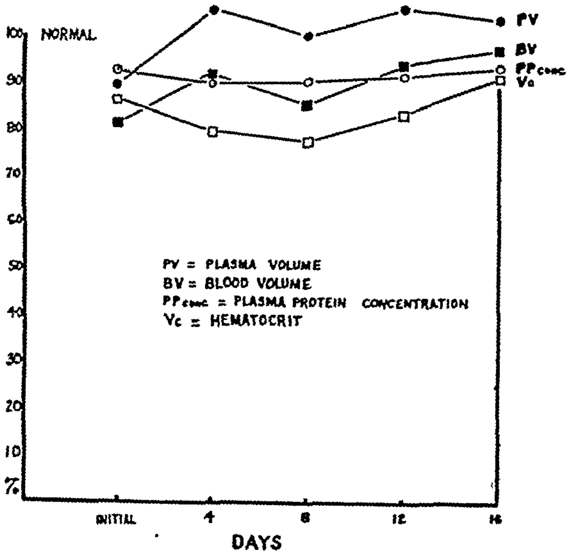

Chart 1.—Data on the blood during wound repair and convalescence.

The data shown graphically in chart 2 suggest that in traumatic shock some correlation exists between the extent of lowering of systolic blood pressure and the degree of oligemia. Line *A* is based on data for 5 patients admitted with systolic blood pressure of zero. Their average initial blood volume was 58.7 per cent, and twenty-four hours later after treatment including surgical intervention the average was 91.7 per cent. Line *B* similarly is based on data for 20 patients admitted with an initial systolic blood pressure of less than 100. The initial average blood volume was 77.5 per cent, and twenty-four hours later it was 87.4 per cent. Line *C* is based on data for 21 patients whose systolic blood pressure at the time of admission was 100 or over. The initial average blood volume was 81.6 per cent, as contrasted with a value of 93.2 per cent twenty-four hours later. Furthermore, if the entire group of severely wounded casualties is divided in this manner according to the initial reading of the blood pressure, it is found that the amounts of plasma and blood administered in the first twenty-four hours showed some correlation with the blood pressure readings. The lower the blood pressure, the greater the amount of blood and plasma considered clinically necessary and given in restorative therapy. The severity of traumatic shock, the extent of reduction in blood pressure, the degree of oligemia and the amount of blood and plasma judged necessary in treatment appear to be related variables in the data from the group studied.

---

[1] Stewart, J. D., and Warner, F.: Observations on the Severely Wounded in Forward Field Hospitals, with Special Reference to Wound Shock, Ann. Surg. **122**: 129 (Aug.) 1945.

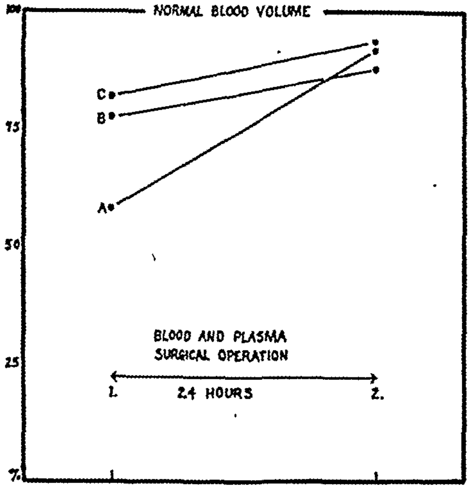

Chart 2.—Blood volume before (point 1) and after (point 2) therapy in wound shock expressed as the percentage of normal.

It is impossible to determine accurately by measurements of the blood volume how much blood has been lost as a result of wounds in any individual case for at least two reasons. The normal value for the particular person cannot, of course, be computed with precision. In the second place life-saving compensatory mechanisms have been activated, and reserves of hemoglobin, plasma protein and fluid have been brought into circulation. However, by the use of average values and a sufficient volume of data some idea can be obtained of the minimum amount of blood which must have been lost to produce the reduction in blood volume which is observed. Table 1 shows an average initial deficit in blood volume of 20 per cent, which amounts to 1,160 cc. when related to the standard average normal for the method. To this must be added 610 cc., which was the average amount of blood and plasma previously administered. This indicates that at least 1,770 cc. of blood had been lost on the average by each patient. To this should be added the unknown but certainly not inconsiderable quantity of mobilized reserves, and it appears likely that the average loss of blood was 2,500 to 3,000 cc., or about half the normal volume of blood.

The picture of traumatic or secondary shock due to penetrating, perforating, lacerating or crushing wounds is subject to considerable variation. The interdependent physiologic responses, largely protective in nature, which color the clinical picture are complicated and as yet imperfectly understood.[31] A typical group of reactions is to be expected, but not enough emphasis has been laid on the frequency with which one or more components is absent. The peripheral veins may be collapsed or full, the skin may be wet or dry, nausea may or may not be present; instead of mental lethargy, alertness and even excitement may be a striking observation. The pulse rate may be normal rather than rapid, and even hypotension may be lacking in a patient who has all the other earmarks of traumatic shock. The life-sustaining adjustments are the reactions of stress, transitory and delicately balanced. Indeed, the most characteristic feature of traumatic shock is the lability of the state and the rapidity with which either improvement under proper therapy or decline may take place. Nevertheless, a reduction of the blood pressure and oligemia were found to be reasonably constant, measurable factors in this group of cases.

The depletion of blood volume in traumatic shock could conceivably be due to loss of water and electrolytes, loss of plasma or loss of whole blood. Accordingly, the concentrations of plasma protein, red cells and nonprotein nitrogen in the plasma were of interest. Values are shown in table 3. It was found that the average concentration of protein in the plasma on admission was 6.5 Gm. per hundred cubic centimeters and that the average red cell hematocrit reading was 37.5 per cent. The average nonprotein nitrogen value in the plasma was 30.8 mg. per hundred cubic centimeters (not shown in the table). These values are to be compared with average normal values for healthy soldiers of a concentration of 7.0 Gm. per hundred cubic centimeters for plasma protein and 43.3 per cent for the hematocrit. The plasma nonprotein nitrogen value offers confirmatory evidence of the absence of anhydremia. Hemodilution, which is a characteristic physiologic response to severe hemorrhage, was a uniform finding in this group of patients. Patients with burns were not included in the study.

Table 3.—*Plasma Protein Concentrations and Hematocrit Values in Normal Soldiers and in Essentially Untreated Wound Shock*

	Plasma Protein Concentration, Gm./100 Cc.				Hematocrit, Percentage			
	After age	High	Low	No. of Observations	Average	High	Low	No. of Observations
Normal.......	7.0	8.0	6.2	42	43.3	50.5	37.5	42
Wound shock	6.5	7.5	5.1	71	37.5	60.0	17.0	86

If one considers the typical hematic changes in wound shock, namely oligemia and reduction in concentration of hemoglobin and plasma protein, there seems to be little room for debate over the relative merits of plasma and blood in repair. The injection of plasma will unquestionably lead to an elevation of blood volume, but only at the price of further dilution of circulating hemoglobin. Theoretically there might be sufficient improvement in the flow of blood to offset temporarily the lowering of the concentration of hemoglobin, but a dangerous and false sense of security would be the result. The evidence indicates that massive quantities of blood have been lost, externally, into body cavities or into damaged tissues. Relief of tissue anoxia under the circumstances is an urgent requirement to be met by replacement of circulating hemoglobin values and improvement in the amount of oxygen carried by the blood.

In connection with the question of the amount of blood and plasma required in the restorative therapy of traumatic shock, it was pertinent to observe the character of the blood during further convalescence. In table 2 are shown data which bear on this point. Average values for plasma protein concentration, hematocrit reading, plasma volume and blood volume are shown in per cent of the standard normal. The same data are shown graphically in chart 1. It is evident that blood volume, plasma protein concentration and the hematocrit reading remained low for days or weeks. Plasma volume, on the other hand, soon became normal or even slightly above normal. Here is seen an interesting physiologic adjustment, if the data can be taken at face value. The persistent deficit of hemoglobin and plasma protein is accompanied by overdilution, and some sacrifice of concentration is made in restoring the volume of blood to normal. Some of these patients received plasma and hemoglobin during convalescence, but it is clear that neither in replacement therapy for shock nor in convalescence were large enough volumes of blood and plasma administered.

The persistence of anemia, hypoproteinemia and oligemia in the severely wounded can be variously explained, apart from the large initial losses of blood involved. Starvation during convalescence, sepsis and abnormal catabolism of protein, losses in weeping wounds and inflamed serous membranes, the demands of wound healing, depression of the bone marrow and liver, and the unexplained large urinary nitrogen losses known to follow trauma all may play a part. Such deficiencies should obviously come under vigorous treatment as a part of the successful management of severe trauma.

A question of critical importance in wound shock is when to proceed with the definitive surgical operation. How long should operation be postponed in the hope that the patient is making further response to blood transfusion, oxygen therapy and the administration of morphine? In many instances the surgical operation itself is essential to resuscitation, especially in continuing internal hemorrhage or in perforations of the intestine through which gross contamination of the peritoneal cavity is taking place, in lacerations of bile ducts or in abdominal evisceration. Clinical evaluation of the individual case rather than any rule of thumb is the principle to be applied, and with increasing experience fewer mistakes are made. The treatment of the state of shock by transfusions of blood and oxygen therapy can be continued during and after surgical intervention, and shock treatment and surgical operation must not be set apart as two different problems. The best results come from fixing responsibility for preoperative care, surgical operation and aftercare on the same surgeon. The continuity of management obtained in this way makes possible intelligent, critical and efficient treatment of the physiologic disturbances as well as the technical surgical problem in the case. In the group of cases under discussion the average interval between admission to a field hospital and surgical intervention was 4 hours. The response of systolic blood pressure, the amount of blood given and the location and suspected nature of the wounds were factors commonly considered in deciding when to proceed with the operation.

Of the 100 gravely wounded patients who form the basis of this study, 17 died under observation in the forward field hospitals. Nine of these deaths occurred within forty-eight hours after admission. Of the 9 patients who survived forty-eight hours or less, 2 died with aspiration of vomitus during anesthesia as a conspicuous phenomenon, 1 had severe blast injury of both lungs, 1 had gross feculent peritonitis from multiple intestinal wounds. This leaves a group of only 5 patients whose death is to be considered in relation to a possible state of "irreversible shock." Persistent hemorrhage and insufficient replacement of blood could not be excluded as likely causes of death in any of these 5 patients. The conception of irreversibility did not, therefore, appear to be an important consideration in these cases.

It should be pointed out that this paper has been largely concerned with wound shock due to severe trauma, not including burns, and for the most part still uncomplicated by such lesions as clostridial myositis, spreading peritonitis or pulmonary thromboembolism. Such complications may produce recurrence of the state of secondary shock as a separate episode, however, distinct from the picture of wound shock.

SUMMARY

In wound shock the usual findings are reduction in blood volume, reduction in plasma protein concentration and lowering of the hematocrit reading. From the data presented it is concluded that loss of blood is the dominant etiologic factor. Anemia, hypoproteinemia and oligemia may persist during convalescence, which points up the need for complete restoration of blood losses during the management of wound shock.

REPLACEMENT OF BLOOD IN MANAGEMENT OF WOUNDS

HOWARD E. SNYDER, M.D.
Winfield, Kan.

Recognition of the extent of loss of blood in the wounded and the all important role this loss plays in traumatic shock has led to an improved and rational program in the management of shock. The war provided many lessons in the management of shock; yet the full significance of these lessons is not widely known.

American forces invaded North Africa in November 1942. Medical department units supporting these troops were well supplied with dried plasma and necessary apparatus to administer this plasma in a most efficient fashion. However, little or no preparation had been made for the administration of whole blood. In these first few months the response of the wounded in shock to the administration of large quantities of plasma was most gratifying. At the same time, however, the need for the transfusion of whole blood in many of the casualties became apparent. In the first three weeks in Oran, Africa, the Seventy-Seventh Evacuation Hospital reported the use of more blood than plasma in the management of battle casualties.[1]

. Read in the symposium on "Wound Management" before *the Section* on Surgery, General and Abdominal, at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

[1] Report 77th Evacuation Hospital to II Corps Surgeon, December 1943.

Early in 1943 in Tunisia, North Africa, where many more fresh battle casualties were admitted to the hospitals, plasma again accomplished much and received considerable praise. Again, however, there were some of the more severely wounded soldiers who did not react from shock with the administration of plasma, while soldiers with similar wounds responded well to the administration of whole blood. It also was noted that those patients who did react from severe shock after the administration of large quantities of plasma presented a severe anemia during their convalescence. After the Tunisian campaign, which ended May 15, 1943, a report from the Second Corps Surgeon to the Surgeon General[2] included the following statements:

Table 1.—*Blood Used in American Forward Hospitals in the North African and Mediterranean Theaters*

	Battle Casualties Admitted	Pints of Blood Given	Percentage Receiving Blood	Pints per Battle Casualty Transfused
Tunisia................	8,019	446	?	?
Sicily..................	3,909	158	?	?
Italy

July-December 1944..	19,522	13,625	30.2	2.31
January-May 1945...	7,967	8,140	40.6	2.52

Data based on reports of hospitals to the Second Corps Surgeon in Tunisia and Sicily and to the Fifth Army Surgeon in Italy.

> The treatment of shock with plasma has produced the most sensational and gratifying results. How many lives have been saved that might have been lost without plasma cannot be adequately determined. . . . Where hemorrhage has been a major factor, whole blood must be used as soon as cross-matching can be completed and an adequate amount transfused. . . . A few lives have been lost and morbidity no doubt increased because blood transfusions have not been used soon enough or often enough. This has been true largely because facilities for blood transfusions have been far from convenient and the importance of whole blood transfusions has been overlooked while stressing the importance and value of blood plasma.
>
> Indirect transfusion sets have been improvised from tubing furnished with plasma, empty glucose and saline solution bottles, glass tubing and aluminum tubing secured from wrecked planes, etc. Distilled water necessary for cleaning bottles and tubing and preparing citrate solution has been procurable only with difficulty. Facilities for cross-matching have often been lacking. Donors have usually been available only from the personnel of the medical units. In spite of all this, blood transfusions have been given in collecting stations, clearing stations, auxiliary surgical group team installations, some semi-mobile evacuation hospitals and 750-bed evacuation hospitals. In the 128th Evacuation Hospital in one campaign, donors were secured from service personnel and kept at the hospital until needed. In the last campaign, a certain number of donors were sent daily or twice daily, blood was drawn as soon as they arrived and then stored in a refrigerator until needed. In most instances it was used immediately or within a few hours. The provision of blood from a blood bank with properly prepared sterile tubing, filters and needles, would serve to make whole blood transfusions almost as convenient as plasma transfusion. A standard method of cross-matching should be prescribed and facilities for the same made available. Proper precautions should be taken to avoid the transmission of malaria and syphilis by blood transfusions.

Table 2.—*Plasma Used in American Forward Hospitals in the North African and Mediterranean Theaters*

	Battle Casualties Admitted	Number Receiving Plasma	Percentage Receiving Plasma	Units per Battle Casualty Admitted

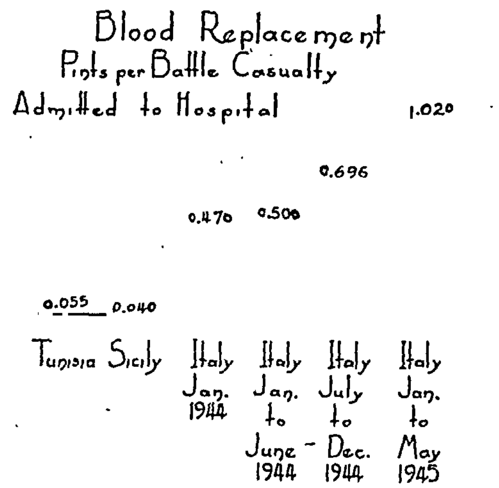
July-December 1944..	19,522	3,212	16.4	0.389
January-May 1945...	7,967	1,711	21.5	0.504

Data based on reports of hospitals to the Second Corps Surgeon in Tunisia and Sicily and to the Fifth Army Surgeon in Italy.

The facilities for the transfusion of blood in Sicily were no better than, if as good as, those available in Tunisia, inasmuch as all the forward hospitals, with one exception, were new units. Experience there led to the same conclusion regarding the need for whole blood.



Blood replacement based on reports from all forward hospitals in the Tunisian, Sicilian and Italian campaigns.

The prolonged campaign in Italy provided the opportunity for improvement in facilities for the transfusion of blood. Even before the establishment of the blood bank, which began delivering blood late in February 1944, hospitals had developed homemade equipment, including homemade vacuum bottles for drawing blood,[3] and established their own blood banks, which made the use of larger quantities of blood possible. Tables 1 and 2 and the accompanying chart give figures on the use of plasma and blood in Corps and Army Hospitals in the North African and Mediterranean theaters of operation.[4] While figures are not available for September to December 1943, it will be seen that by January 1944, before the blood bank was in operation, blood was being used at the rate of 0.474 pint (224 cc.) per battle casualty admitted to the hospitals. In the latter part of February 1944 the first blood was delivered from the American Blood Bank to Fifth Army units at Anzio, Italy. In the period from January to June, 1944, the consumption rose to 0.5 pint (237 cc.) per battle casualty admitted. In the next six months it rose to 0.696 pint (330 cc.) per battle casualty and in the five months of the war in 1945, 1.02 pint (483 cc.) per battle casualty admission was used. It is also interesting to note that in this period the percentage of battle casualties receiving blood rose from 24.2 per cent in January 1944 to 40.6 per cent for the year 1945.

TABLE 3.—*Percentage of Deaths in Hospital Battle Casualty Admissions*

	Jan.-March 1944	April-July 1944	Aug.-Dec. 1944	Jan.-May 1945	Total
Percentage dying before anesthesia	1.390	0.680	0.440	0.440	0.752
Percentage dying during anesthesia or surgical operation	0.211	0.141	0.171	0.165	0.167
Percentage dying after anesthesia or surgical operation	2.340	1.620	1.440	1.435	1.671
Total percentage dying in hospital	3.940	2.340	2.050	2.040	2.590

Based on study of 1,411 American battle casualty deaths reported by Fifth Army hospitals Jan. 1, 1944 to May 2, 1945.

The increased use of blood accounted in great part for the reduction in mortality depicted in table 3.

At the same time the use of plasma continued to approximate the figure first attained in the Sicilian campaign when 20.2 per cent of battle casualties were administered plasma. The average amount of plasma given per battle casualty admitted to hospitals likewise varied little from 0.5 of one unit (250 cc.).

The figures given are for the use of plasma and blood in forward hospital installations. With the exceptions of the period in Tunisia when hospitals were far back and one period in Italy when the line was advancing rapidly and blood was furnished to a treatment station of the First Armored Division, the use of blood was restricted to hospital installations, and plasma alone was available in aid stations, collecting stations and clearing stations.

The use of large quantities of plasma in resuscitation of a patient prior to his admission to a hospital often rendered the problem of preparing the patient for surgical intervention more difficult. It was the general feeling that only enough plasma should be given to render the patient transportable to the hospital where whole blood might be used in further resuscitation.

The work of competent investigators did much to improve the management of shock in battle casualties in Italy, furnishing the basis for a revision of ideas on the etiology and treatment of shock and leading to the use of larger quantities of blood. In December 1943 Lalich[5] began to conduct a scientific clinical appraisal of battle casualties in shock and made recommendations which proved sound in the light of laboratory investigations on hematocrit and plasma protein levels which he conducted at Anzio in the spring of 1944. In January 1944 on the Cassino front, Stewart and Warner[6] made the first studies on blood volume and hematocrit and plasma protein determinations in battle casualties. Beecher and Burnett[7] provided further clinical studies with hematocrit and plasma protein determinations on all the most severely wounded soldiers admitted to the Ninety-Fourth Evacuation Hospital. Finally, the work of the Commission for the Study of the Seriously Wounded headed by Simeone,[8] covering the period from autumn 1944 until termination of the war, provided more complete data on the loss of blood and of plasma and the problem of post-traumatic anuria or pigment nephrosis. The results of these investigations became known and were utilized long before any reports were submitted or published.

The laboratory and clinical observations allow the following conclusions to be drawn: 1. Lowered blood volume in the shock of battle casualties is due entirely to the loss of whole blood and not to loss of plasma except in those cases in which there is gross peritoneal or pleural contamination, beginning sepsis, gas gangrene, a burn or a crush injury. 2. When whole blood has been lost, whole blood is the replacement medium of choice, particularly when the loss has been large.

While reduced blood volume is usually the most important etiologic factor in shock, it is often not the only factor. Cardiorespiratory embarrassment may be an extremely important factor in many cases of shock and when present must be managed with the same promptness as is reduced blood volume.[9] A sucking wound of the chest, a painful wound of the thoracic wall hindering the respiratory movement, a large amount of blood or air in the pleura, a dilated stomach, cardiac tamponade and the presence of blood and mucus in the tracheobronchial tree are all conditions which demand immediate attention in the person who is in shock.

Gross contamination of the peritoneal and pleural cavities with contents of the gastrointestinal tract and early sepsis in these cavities or in any wound constitute other important factors in shock and demand early surgical intervention for relief.

Pain likewise contributes to shock. The judicious use of a salt of morphine, the proper splinting of wounds of the extremities, nerve block with procaine hydrochloride and early surgical intervention are used in its control.

TABLE 4.—*Etiologic Classification of Shock in Five Hundred and Twenty-Three Fatal Cases*

	No. of Cases
Trauma and hemorrhage	182
Trauma and hemorrhage plus contamination or sepsis	120
Trauma and hemorrhage plus cardiorespiratory embarrassment	147
Trauma and hemorrhage plus contamination or sepsis plus cardiorespiratory embarrassment	72
Type undetermined	2
Total	523

Shock may be divided into four broad categories on the basis of etiologic factors: (1) trauma and hemorrhage alone; (2) trauma and hemorrhage plus contamination or sepsis; (3) trauma and hemorrhage plus cardiorespiratory embarrassment, and (4) trauma and hemorrhage plus contamination or sepsis, plus cardiorespiratory embarrassment. Table 4 shows the distribution of shock among these four categories in 523 casualties in which the immediate cause of death was shock.[10]

Blood replacement therapy must be integrated in a program dealing with all etiologic factors in shock. Surgical intervention is an essential part of this program. It frequently must be performed before the person is completely resuscitated from shock and as a part of the resuscitative program.

Immediately on the admission of a battle casualty or any wounded person, a rapid complete appraisal or examination must be made to determine: (1) the blood pressure and pulse rate, (2) the nature and extent of the wounds, (3) the probable extent of loss of blood, (4) the presence or absence of wounds, injuries or conditions leading to cardiorespiratory embarrassment, (5) the possibility of contamination or sepsis in the peritoneal or pleural cavities, (6) the presence or absence of early sepsis or gas gangrene in any part of the body and (7) the presence or absence of pain.

As this primary examination is rapidly made, indicated resuscitative measures are initiated. The head is lowered and blankets are applied to conserve body heat. (The application of external heat has been found undesirable.) In those persons in whom a blood pressure reading cannot be obtained, administration of low titer group O blood should be immediately started through a cannula in a vein at the ankle. The first 500 cc. of this blood may be given in as short a time as five to ten minutes, and if there is no response of blood pressure to this, the next 500 cc. may be given as rapidly. (All blood after the first 1,000 cc. must be cross matched.) Once a systolic blood pressure of 70 mm. of mercury has been obtained, the rate of transfusion should be decreased. In these patients in severe shock, the administration of oxygen is always indicated. If a systolic blood pressure of 50 to 60 mm. of mercury cannot be obtained by the rapid administration of 1,000 to 1,500 cc. of blood, immediate surgical intervention may be indicated to control continuing hemorrhage or to deal with gross contamination of the peritoneal and/or pleural cavities or perhaps to excise tissue or a limb rendered necrotic by clostridial myositis. Meanwhile, the transfusion of blood should be continued while the patient is moved to the operating table, as an interruption in the administration of blood in those patients with continued bleeding or in those in whom ample blood has not been replaced may lead to a dangerous, undesirable drop in blood pressure. It is well to have the cannula in place with blood running in, particularly in abdominal and thoracic wounds, so that in the event of any loss of blood at the time of the surgical intervention, it may be immediately replaced by the use of pressure, if necessary, to secure the desired rate of flow.

Observations at operation may dictate the type of further replacement therapy. In abdominal wounds, peritonitis and/or gross contamination of the peritoneum with feces without much blood in the peritoneum calls for plasma therapy rather than for the administration of more blood.

It has been found desirable to administer 1,000 cc. more blood or plasma after the systolic blood pressure approximates normal. This rule applies as well in those cases in which the shock is not of such severity. In the management of shock of less severe grade, all blood is cross matched. One or two units of plasma (500 to 1,000 cc.) may be given while this is being accomplished. The blood is then given less rapidly, usually at a rate approximating 1 pint (473 cc.) in thirty minutes.

While plasma or blood is running in, other indicated procedures are performed. Aspiration of hemothorax, pneumothorax or hemopericardium is accomplished. Uncontaminated aspirated blood may be filtered and autotransfused. Blood and mucus in the trachea and bronchial tree may be aspirated by tracheal catheter or bronchoscope if the patient cannot cough them up.

Pain may be relieved, deep breathing promoted and cough facilitated in painful wounds of the chest by procaine hydrochloride block of the involved intercostal nerves. Small doses of a solution of a salt of morphine and atropine administered by the intravenous route may be indicated. Continued bleeding in an extremity may call for the use of the tourniquet. The tourniquet is also used at or below the contemplated site of amputation in limbs hopelessly damaged by trauma or infection. Painful wounds of the extremities must be properly splinted. A nasogastric tube is passed in all thoracic and abdominal wounds. Preoperative roentgenologic examination is desirable in all cases. It is occasionally omitted in instances where emergency surgical intervention cannot be delayed. In many cases blood transfusion is continued without interruption throughout the radiologic examination, the trip to the operating table and the surgical procedure. The use of a cannula tied in a vein is most satisfactory in such cases. The practice of cutting down on a vein and tying in a cannula became routine and was felt to be timesaving in all who were admitted with collapsed veins. With a cannula in place. blood could be pumped in at any desired speed. This latter procedure is not without danger and should be reserved for emergencies only. One case of fatal air embolism was reported as resulting from this practice. when it was not noticed for a few seconds that the bottle had emptied of blood.

Lalich and Mason [5b] have called attention to the need for the replacement of blood in that group of casualties in which there is impending peripheral circulatory failure. Those patients whose systolic blood pressure is 90 or more and whose pulse rate is a little rapid but who have wounds of such an extent and number as to indicate impending shock should be given a transfusion of 1,000 cc. of blood prior to surgical intervention. When this has not been done, precipitous falls in blood pressure have occurred during radiologic examinations or surgical operation. Traumatic amputations frequently fall in this group.

Further transfusion of whole blood is frequently necessary in the postoperative period, during which all observers have noted the appearance of anemia. An effort was made to secure normal hematocrit readings on all patients with severe abdominal and thoracic wounds early in their postoperative course. In those with less severe wounds, it was felt desirable that the hematocrit readings should be at least 35 before the patient was evacuated.

---

[10] Snyder, H. E., and Culbertson, J. W.: Study of Fifth Army Hospital Battle Casualty Deaths: A Preliminary Report to the Surgeon, Fifth Army, September 1945.

Forward hospitals actively engaged in caring for battle casualties are ideally furnished with blood from a base transfusion unit well in the rear. The blood furnished is all group O but titered for anti A and anti B agglutinins. When these agglutinins are in a titer greater than 1 to 64, the bottle is labeled for group O recipients only. Low titer group O blood, or blood in which the anti A and anti B agglutinins are present in a titer less than 1 to 64, is reserved for group A, group B and group A-B recipients and for use in emergencies without cross matching in amounts up to 1,000 cc. The blood used in the Mediterranean theater was drawn in Baxter vacuum bottles containing citrate, and after drawing the blood the bottles were topped with dextrose solution as a preservative. All blood was used within seven days of the time it was drawn. It was carefully checked for group by at least 2 persons on two different specimens. The contents of every bottle were also checked for syphilis and malaria, and blood was not drawn from donors who gave a history of jaundice, malaria or syphilis. To each bottle of blood was attached a small bottle of uncitrated blood which was used for cross matching. The blood was refrigerated immediately after it was drawn and was transported in cork-insulated boxes when it had to be flown to the front. When deliveries could be made by truck from the base transfusion units, the blood was kept in a refrigerator right up to the time it was delivered to the hospitals where, of course, it was immediately placed in another refrigerator.

The transfusion of whole blood was found to be a most essential measure in the management of battle casualties in the general hospitals in the base, prior to and during the time of reparative surgical intervention. Lyons and Hampton [11] definitely demonstrated the value of the transfusion of large quantities of whole blood along with penicillin therapy in preparing battle casualties for reparative operations. Five hundred to 1,000 cc. of blood was given daily until normal hematocrit readings were obtained. This regimen, followed by surgical procedures designed to remove all necrotic tissue, clots or exudate and to eliminate dead space, led to remarkable results in infected or otherwise complicated wounds.

In 1944 and 1945, 68 patients are known to have died in Fifth Army Hospitals of a pigment nephropathy or nephrosis of the lower part of the nephron. In 31 other cases nephrosis contributed to death.[9] A few of these cases were due primarily to the administration of sulfonamide compounds. A few were known to be due to mismatched transfusions. Extensive work on this subject by the Commission on the Study of the Seriously Wounded [7b] would indicate that in the vast majority of instances the transfusion of blood was not the underlying factor, but that the condition was due to other factors probably depending on a severe degree of shock over a considerable period of time. In those instances in which pigment nephropathies developed in the wounded who had received group O blood from the base blood bank, it was found that the incidence of nephropathy in the four groups of blood paralleled the normal incidence for each of the blood groups.

The blood bank furnished blood only to the forward hospitals. It was considered desirable even in forward evacuation hospitals to have facilities at hand at all times for the grouping and cross matching of type-specific blood drawn on the spot, so that in the event of failure to deliver blood from the blood bank, facilities for the transfusion of blood would not be entirely lacking. In the general and station hospitals in the base, each hospital maintained its own blood bank of type-specific blood. It is not the purpose of this paper to discuss the merits or demerits of universal donor blood versus type-specific blood in installations when time and facilities permit the use of the latter. However, it is definitely established that in forward hospitals receiving large numbers of battle casualties fresh from the field, the use of group O universal blood is much preferred to the use of type-specific blood.

The advantages of adequate blood replacement with whole blood are manifold. Mortality from shock is lowered. Prolonged adequate surgical intervention is possible when the replacement of blood is adequate. Operations which lasted three to five hours were not uncommon; in a number of instances they lasted even longer with satisfactory results. In the early days a few wounded persons lost their lives because surgical intervention was inadequate or was cut short due to the patient's poor condition and to the fact that gas gangrene later developed in an undebrided or inadequately debrided wound. Adequate replacement of blood shortens convalescence. It reduces morbidity. It permits early radical reparative surgical operations.

Lessons learned in the management of battle casualties insofar as the replacement of blood is concerned have their application in civilian surgical practice. It is desirable to have low titer group O blood available for use in emergencies which occur with severe wounds or with emergencies which occur because of unexpected bleeding at the operating table. It is desirable to replace all lost blood with whole blood. It is desirable to start all elective surgical intervention with a normal blood count and blood volume. In emergency operations an effective volume of circulating whole blood should be secured by the time the operation is completed or shortly thereafter. Repeated transfusions of blood to maintain a normal hematocrit or blood count are desirable in all cases of infected or complicated wounds.

SUMMARY

Adequate timely replacement of blood was an exceedingly important factor in the reduced mortality of battle casualties admitted to hospitals in World War II. Clinical observation followed and substantiated by laboratory investigation led to the recognition of the loss of whole blood rather than of plasma as the cause of reduced blood volume in most cases of shock encountered in the wounded. Rapid replacement of whole blood properly coordinated with other resuscitative measures (including surgical intervention) was found essential to the successful management of those patients in severe shock. Adequate replacement of blood not only tended to lower mortality but decreased morbidity, hastened convalescence and permitted extensive early reparative surgical operations. In forward hospitals banked group O blood titered for anti A and anti B agglutinins was found most satisfactory. Methods of blood replacement developed in the management of battle casualties can be applied in civilian surgical practice.

103½ East Ninth Avenue.

THE BACTERIOLOGY OF OPEN WOUNDS

ROBERT RUSTIGIAN
Medford, Mass.
and
ARTHUR CIPRIANI
Brooklyn

Bacteriologic studies in Italy and elsewhere[1] during the late war have confirmed the presence of diverse bacteria in war wounds. As part of a study of penicillin therapy in the management of wounds in Italy a total of 214 types of bacteria were isolated from 27 infected and 9 clinically clean wounds.[2] The decidedly anaerobic environment of the bacteria in these traumatic injuries was emphasized by the fact that 45.3 per cent, or 97 of the 214 isolates, representing several genera, were obligatory anaerobes and 15.9 per cent, or 34 cultures, namely streptococci and micrococci, were microaerophiles. Eleven defined and 5 arbitrary groups were represented. From 8 to 10 species or types were recovered from 10 of the infected wounds, at least 5 from 21 and no less than 3 species or types were recovered from any 1 of the infected wounds. The clean wounds differed from the infected wounds in the absence of pyogenic cocci. This difference may be associated with the time of the study after injury, since the average time was six days for the clean wounds as compared to twenty-three days for the infected wounds.

The technical procedures of isolation and study of the cultural, physiologic and toxic properties of the various bacteria are embodied in another report.[3] It is known that some obligatory anaerobes, including bacilli, cocci and fusobacteria, are fastidious nutritionally and grow slowly on complex mediums.[4] Technical difficulties are further introduced by the ability of Proteus and many species of Clostridium to spread on solid mediums. In view of such facts and certain observations, no claim is made that the isolation of all bacteria in each of the wounds was successful.

Although the bacterial flora of war wounds is complex, the frequency of isolation of certain bacteria in this and other studies of both war and accidental wounds[5] permits, within limits, delineation of characteristic wound floras. Beta hemolytic streptococci, Staphylococcus aureus, Staphylococcus albus, enteric streptococci, Clostridium, *Proteus*, *Pseudomonas* and coliform bacteria appear to be the species most frequently encountered. Other types less frequently reported include undifferentiated streptococci, anaerobic streptococci, micrococci, bacteroides, diphtheroids and bacilli. A characteristic wound flora may signify that there are limitations to the types of bacteria which find an environment suitable to their growth and nutritional requirements. The predominance of certain species at various stages of an infection or with certain types of infection might denote, in part, a more optimal nutritional substrate for their differential metabolic needs.

It is not emphasized sufficiently that defined pathogenic bacteria may comprise part of the wound flora without manifesting their cardinal clinical attributes. Recently proteolytic bacteria without defined pathogenicity have gained clinical importance in infected wounds. Lyons has reported[2] that through septic decomposition of devitalized tissue by proteolytic bacteria the necrosis of living tissue may occur as a secondary consequence. Any further references to clinical data unless otherwise noted are taken from Lyons' studies which constitute the clinical counterpart of this bacteriologic report.

In view of the foregoing considerations, the 214 bacteria isolated were differentiated under three functional entities: (1) toxigenic and/or invasive, (2) proteolytic and (3) wound commensals (table 1).

The proteolytic bacteria were defined by their ability to attack one or more of the following protein substrates: cooked meat medium, Loeffler's blood serum medium (Difco), fibrin clot, casein[6] and gelatin. Those bacteria which did not attack these substrates but which produced hydrogen sulfide and/or visible gas from secondary protein derivatives were differentiated under the proteolytic group (table 2).

Because of their observed role in local necrosis the bacteria which hydrolyzed proteins were designated as

wound pathogens, thus denoting their clinical significance but at the same time differentiating them from invasive and defined toxic bacteria. The commensal group included those bacteria which could not be allocated to the true pathogens or proteolytic group. They probably utilize part of the nutritional complex of wound substrates but by themselves do not appear to be significant clinically. It becomes apparent that with strain differences among certain species or types inconsistencies will occur between their taxonomic and functional segregation. For example, 1 strain of aerobacter which liquefied gelatin was placed in the proteolytic group while 7 others which were negative for the liquefaction of gelatin were placed in the commensal group.

Fourteen strains of Staph. aureus and 7 of beta hemolytic streptococci were recovered from 19 infected wounds. All strains of Staph. aureus except one were hemolytic on blood agar at 37 C., and 11, including the nonhemolytic strain, were coagulase positive. Six strains partially attacked fibrin clot; 8, including 3 of the fibrinolytic strains, liquefied gelatin. Seven strains showed positive correlation for pigment production, hemolysis (37 C.), coagulase activity and mannitol fermentation. Five of the 7 beta hemolytic streptococci were available for further study. Four belonged to Lancefield serologic group A and one to group C. The proteolytic activity of the hemolytic streptococci was limited to fibrinolysis in this study.

All other cocci were placed in either the proteolytic or the commensal group (table 1). Three Staph. albus and 2 nonpigmented staphylococci were neither hemolytic nor coagulase positive. One strain of each liquefied gelatin. In addition to the pyogenic streptococci, 22 enteric streptococci, 17 undifferentiated nonhemolytic streptococci and 8 anaerobic streptococci were recovered. The enteric streptococci were isolated from 22 wounds, including 5 clean ones, and were surpassed in frequency of isolation only by species of Clostridium. Nine cultures were isolated by direct aerobic plating and 4 by aerobic plating from anaerobic broth. The remaining 9 cultures could be isolated only by anaerobic plating from anaerobic broth but did grow aerobically with the first subculture. Similar relationships were found among the undifferentiated streptococci. These results suggest degrees of adaptation between aerobic and anaerobic environment. Three of the 22 enteric streptococci were hemolytic on blood agar. All but 1 culture were placed in the commensal group. The single proteolytic type liquefied gelatin, caused some digestion of casein and slightly liquefied Loeffler's blood serum medium.

The 17 undifferentiated streptococci recovered from 11 of the infected and 3 of the clean wounds were classified as commensals. One culture produced weak hemolysis on isolation but was negative on subsequent platings and gave no reaction in Lancefield's grouping serums A, B and C. Eleven cultures were microaerophilic. Eight of these demonstrated some fastidious nutritional requirements in that they failed to grow in 1 per cent Bacto-tryptose broth with 0.3 per cent beef extract and 0.5 per cent sodium chloride. Fermentation tests were valueless for further definition of types in the group. It is possible that a few of the cultures which demonstrated carbohydrate activity might be similar to members of the lactic acid group of streptococci.[7]

Eight anaerobic streptococci were recovered from 6 of the infected wounds and 1 from a clean wound. Isolated colonies did not show hemolysis, although 4 cultures produced hemolysis at the heavily crowded area of streak plates. The same 4 cultures were proteolytic, although their reactions were delayed. They caused digestion of milk of iron and casein (seven to fourteen

days) and Loeffler's blood serum (twenty-one to thirty days); they liquefied gelatin (seven to twenty-one days), gave a weak to moderate hydrogen sulfide reaction (seven to fourteen days) and formed indole. However, they failed to produce fibrinolysin. One other culture caused lysis of fibrin clot and formed gas consistently in carbohydrate-free mediums. The remaining 3 cultures failed to demonstrate significant activity on fermentative, proteolytic and other test substrates. None of the 8 anaerobic streptococci conformed culturally and biochemically to the 8 anaerobic species listed by Prévot,[8] including those associated with gangrene. Topley and Wilson[9] were of the opinion that the anaerobic streptococci comprise many different groups, species and types for which there is not sufficient data at present to permit systematic classification.

Cocci other than staphylococci and streptococci were designated as micrococci and constituted a heterogeneous group. Diplococci, tetrads and cocci arranged singly or in clumps represented the arrangement of types. Thirty-six cultures were recovered from 21 wounds, including 2 clean ones. Preliminary studies failed to classify these organisms. Twenty-one cultures from 19 wounds were obligatory anaerobes, 14 cultures from 13 of either the same or different wounds were microaerophilic and 1 culture was aerobic. None of the cultures was hemolytic, and their biochemical reactions were limited and variable. Eleven of the 14 microaerophilic micrococci failed to grow in the 1 per cent Bacto-tryptose broth with 0.3 per cent beef extract and 0.5 per cent sodium chloride, but by increasing the Bacto-tryptose concentration to 5 per cent, moderate growth was obtained in forty-eight hours with all but 2 cultures. All the microaerophiles were placed with the commensals, but 7 of the anaerobic micrococci exhibited some degree of proteolytic reaction (table 2). Technically, the micrococci had a high nuisance value and were often responsible for repeated platings to purify clostridiums.

Twenty-five cultures of gram-negative nonsporulating aerobic bacteria were isolated from 20 wounds including 3 clean wounds. The majority proved to be members of the family Enterobacteriaceae[7] and were identified as follows: 8 strains of Aerobacter, 2 Escherichia, 4 paracolon Aerobacter,[10] 2 paracolon Escherichia and 2 Proteus. Four cultures were Pseudomonas aeruginosa. Three unidentified cultures previously encountered in wound infections[11] were the same culturally and biochemically. Dark pink convex colonies with their margin entirely to slightly irregular were formed on eosin–methylene blue agar, and a mucoid-like growth occurred on nutrient agar. They were nonmotile. Glucose was fermented with acid production in twenty-four hours, but lactose, sucrose, salicin, maltose and mannitol were not fermented after two weeks. Indole and Voges-Proskauer tests were negative, but growth occurred on citrate agar. They were not proteolytic. Stuart and Van Stratum[12] reported the isolation from infants of unidentified organisms which fit this description except for delayed lactose fermentation. Proteus and Pseudomonas were the most active proteolytic bacteria of this group. Next to certain species of Clostridium the most actively proteolytic type encountered was Proteus. Among the coliform and related bacteria 1 strain of Aerobacter and 4 of paracolon Aerobacter were placed in the proteolytic group because they liquefied gelatin.

Three strains of the nonsporulating anaerobe Bacteroides melaninogenicum were isolated from infected wounds. In serum broth they produced an irregular flocculation accompanied by a strong odor of hydrogen sulfide, while in blood broth there was pronounced darkening with loss of opacity. The 3 strains were difficult to maintain and were lost before their proteolytic reactions were studied. On the basis of their reactions in serum broth and blood broth and their described proteolytic features[13] they fell readily into the proteolytic group. It is possible that the incidence of this organism is low since its presence was suspicious in smear from several other specimens (characteristic gram-negative bipolar staining rods in preliminary enrichment broth smears of infected material) and it required prolonged cultivation for isolation.[4]

Species of Clostridium comprised the most numerous group recovered. Fifty-eight cultures representing 8 species and 9 unidentified types were recovered from 26 of the 36 wounds, an incidence of 72.2 per cent. Ten species or types, including toxigenic types, were isolated from 5 of the 9 clean wounds. Toxigenic species included 7 Clostridium perfringens, 2 Clostridium novyi and 2 Clostridium septicum strains and 1 type which resembled but could not be identified definitely as Clostridium fallax. Except for Cl. perfringens their toxicity was demonstrated by guinea pig inoculations. All the Cl. perfringens strains, however, were positive for alpha toxin as determined by a modified Nagler reaction.[14] Twenty-two Clostridium sporogenes were isolated, an incidence of 61.1 per cent from all wounds and 84.6 per cent from the wounds from which types of Clostridium were recovered. The remaining species included 1 Clostridium bifermentans, 1 Clostridium sphenoides, 6 Clostridium tertium and 8 Clostridium putrificum and related types.[4]

The discrepancies found among given characteristics of species of Clostridium and the occurrence of unidentified types in this and other recent studies[15] reflect some problems of this group. The described characteristics of Clostridium sordelli by Reed and Orr[16] are identical to those of Cl. bifermentans except for hemolysis and toxin production by the former. Bergey's Manual,[7] on the other hand, describes Cl. bifermentans as hemolytic and considers "Bacillus sordelli" a toxic strain of Cl. bifermentans. The single strain of Cl. bifermentans isolated in this study was strongly hemolytic but failed to prove toxic to guinea pigs. One culture was identical with Clostridium capitovalis but failed to ferment galactose or to digest Loeffler's blood serum, and it produced indole.[17] Two strains of Cl. novyi did not produce changes in milk of iron, although reactions of digestion and late coagulation have been observed for this species.[18] Both strains exhibited definite double zone hemolysis, a feature ascribed only to Cl. perfringens of the gas gangrene bacilli. Except for variable salicin fermentation and failure to reduce nitrate, the unidentified toxigenic type was identical to Cl. fallax. Cl. tertium is described as microaerophilic, but 4 of the 6 cultures with the characteristics of this species were anaerobic. These biochemical and metabolic discrepancies may represent strain differences among species of Clostridium, similar to those described in other bacterial groups and types. By nature Clostridium appears to be a complex group. Only when a vast number of stock cultures and freshly isolated cultures are examined under both uniform and controlled variations of test substrates may some of their discordant features be settled. The occurrence of unidentified types in wounds is not surprising in view of the large number of species and types already described.[8]

[17] Prévot.[8] Reed and Orr.[16]

The distribution of species of Clostridium in each of the 26 cases was represented as follows: 5 types from 1 case, 4 from 2 cases, 3 from 7 cases, 2 from 8 cases and 1 from 8 cases. Only 2 of the 10 wounds from which toxigenic types of Clostridium were isolated were diagnosed as or gave a past history of clostridial myositis. These observations support the evidence that toxigenic Clostridium may be present in wounds without eliciting myositis. Furthermore, Cl. perfringens, Cl. novyi and the unidentified type were found in infected wounds seventeen to forty-five days after the time of injury. Two strains of Cl. perfringens and both strains of Cl. septicum were isolated from 3 clean wounds, all of which were under penicillin therapy.

All but 11 of the 58 cultures of Clostridium exhibited some degree of proteolytic activity varying from active digestion of all test substrates by Cl. sporogenes to only fibrinolysis by the unidentified toxigenic type (table 2). The 11 negative cultures, mostly formers of terminal spores, produced hydrogen sulfide from a lead acetate medium. In addition, 3 of the 6 strains of Cl. tertium formed a slight amount of gas from proteose peptone broth. With some variation in the rate of activity the 22 strains of Cl. sporogenes actively digested cooked meat, casein, Loeffler's blood serum, lysed fibrin clot and liquefied gelatin and formed abundant hydrogen sulfide and comparatively large amounts of gas from proteose peptone broth. Weinberg, Nativelle and Prévot [4] have described Cl. sporogenes as the organism par excellence of putrefaction. Its vigorous decomposition of varied protein substrates and its overall active metabolism are so striking that along with its relatively high frequency in wounds, as observed in this and other studies,[15] it may well function as one of the most efficient wound pathogens among the proteolytic bacteria. The decided ability of Cl. sporogenes to produce gas from proteins and glucose may indicate, under appropriate conditions, its role in the formation of gas in infected wounds. In 2 suppurative wounds with gas, Cl. sporogenes was the only active gas-forming member isolated. Further studies of this species appear necessary.

A majority of the 8 cultures of Cl. putrificum attacked most if not all the protein substrates, although their activity was not as rapid or pronounced as that of Cl. sporogenes. One culture actively digested cooked meat in five days and 5 cultures required twenty-one to thirty days for partial digestion of this medium. All 8 cultures liquefied gelatin in from twenty-four to forty-eight hours; casein was digested in from two to seven days, and 7 cultures gave positive reactions on Loeffler's blood serum after from two to three weeks. Four cultures lysed fibrin clot after overnight incubation. All of the bacilli which cause gas gangrene exhibited some proteolytic activity (table 2). Positive but inconsistent results were obtained for fibrinolysis. All strains of Cl. novyi and Cl. septicum and the unidentified type gave positive reactions on one occasion and negative reactions on others. Similar results were obtained with 3 of the 7 strains of Cl. perfringens, while 4 strains were consistently negative.

The remaining bacteria isolated were 4 anaerobic Actinomyces, 3 aerobic spore-forming bacilli, 6 aerobic and 2 anaerobic diphtheroids, 1 alpha hemolytic streptococcus and 2 unidentified aerobic nonsporulating gram-positive rods. The Actinomyces cultures were proteolytic and appeared to be identical. The aerobic spore-forming bacilli diphtheroids, alpha hemolytic streptococcus and aerobic gram-positive rods were not further studied and were arbitrarily placed in the commensal group. Fusiform bacteria were seen in smear from 2 wounds but were not isolated.

COMMENT

In analyzing the functional differentiation employed for the 214 types of bacteria it is noteworthy that bacteria producing proteolytic enzymes occurred with relatively high frequency. Of 193 of the 214 isolates tested, 33.2 per cent without defined pathogenicity digested one or more of the protein substrates. This incidence is increased to 47.7 per cent when the proteolytic reactions of true pathogens are included. In addition, 8.7 per cent of the cultures which did not attack the protein substrates produced hydrogen sulfide and/or visible gas from secondary protein derivatives. The qualitative and quantitative variations of protein decomposition among the various proteolytic bacteria might signify a differential importance in relation to their activity in wounds. Obviously there is no comparison between the proteolytic activity of such organisms as Cl. sporogenes and those organisms whose activity is limited to gelatin liquefaction, such as Aerobacter. However, the proteolytic bacteria were mixed in 22 of the 32 wounds from which they were isolated; there were 9 cases with 2 types and 13 cases with 3 to 5 types. Although sluggishly proteolytic bacteria such as Cl. putrificum may not seem as important as more active types, their proteolytic degradation in vivo could be more active than that suggested by their in vitro metabolism. Their proteolytic activity might be enhanced in association with certain other bacteria. For example, Sturges and Rettger [19] found that the presence of Staph. aureus accelerated considerably the decomposition of protein by B. putrificus.

The defined pathogenic features of Staph. aureus, beta hemolytic streptococci and toxigenic strains of Clostridium should not mask the study of their proteolytic activities. Although the coagulase test is considered indicative of the pathogenicity of Staph. aureus, the liquefaction of gelatin and fibrinolysis by some strains of this species may be important characteristics in relation to their activity in wounds. Of the 3 coagulase-negative strains, 1 liquefied gelatin and was fibrinolytic and 2 were fibrinolytic. The beta hemolytic streptococci were limited to fibrinolysis in the present study. But Christensen[20] reported that a mixture of streptococcic fibrinolysin and the lysin factor of serum caused active proteolysis of casein, gelatin and hemoglobin. The fibrinolysis of other bacteria should be studied to determine whether the active digestion of various proteins occurs under the same conditions. Differences in proteolytic activity among strains, as illustrated by Staph. aureus and other bacteria, should always be kept in mind. The 2 strains of Cl. novyi liquefied gelatin but did not digest milk of iron, although the latter reaction has been described as rapid for this organism.[16] There is no evidence for the action mechanism to account for the local necrotizing action of proteolytic bacteria through the septic decomposition of dead tissue. It is known that bacteria, particularly anaerobic bacilli, are capable of forming as protein degradation products such substances as cadaverine, skatole and indole, which have been associated with systemic toxicity, and others, such as the amine of tyrosine, which cause decided physiologic action in an extremely small concentration.

[18] Topley and Wilson.[9] Reed and Orr.[16]

[19] Sturges, W. S., and Rettger, L. F.: Methods for the Isolation and Cultivation of Bacillus Putrificus and Other Obligate Anaerobes, J. Bact. 4: 171, 1919.

It is more difficult to analyze definitively the wound activity of the various bacteria considered as wound commensals. With further studies some members of this group, such as the anaerobic or undifferentiated streptococci, may be incriminated; but at present there is a lack of evidence that they are involved primarily in the infection of wounds. Almost without exception commensals, including enteric and undifferentiated streptococci, microaerophilic and anaerobic micrococci, a nonpigmented strain of Staphylococcus and aerobic spore-forming bacilli, were the only types isolated from 4 clean wounds which healed without infection[4] in the absence of penicillin therapy. Such bacteria may survive and grow in wound exudates and also in the crevices of traumatized injuries until the healing processes have progressed sufficiently to eliminate them. The hardy characteristics of Streptococcus faecalis might suggest a high degree of adaptability in a wound environment. It is possible that at least some commensals may be of importance through synergistic relationships with the true pathogens and proteolytic bacteria. The synergistic relationship between an anaerobic or microaerophilic streptococcus and a hemolytic Staph. aureus causing postoperative synergistic gangrene has been described.[21] Moreover, the ability of some members to play an intermediate role in the decomposition of dead tissue cannot be overlooked. Amino acid metabolism such as the decarboxylation of tyrosine by Str. faecalis, the breakdown of tryptophan to indole by Escherichia coli and similar reactions by other bacteria placed in the group may contribute to the ultimate decomposition of devitalized tissue.

The combination of the various bacteria in each of the 36 wounds has been reported previously.[2] In the final analysis the interplay of metabolic activities of the true pathogens, the proteolytic bacteria and those regarded as wound commensals may be of major importance in the development of infection. Although the etiologic factors of clinical entities such as myositis and acute cellulitis may be fixed, synergism of concomitant bacteria may affect their degree of infectivity. Updyke and Frobisher[22] produced evidence supporting the view that hemolytic streptococci of group B may act synergistically with diphtheria bacilli to cause malignant diphtheria in certain cases of the disease. MacLennan[1] noted a greater fatality rate in gas gangrene due to mixed infections of toxigenic strains of Clostridium than in that due to infection by a single species. In addition he obtained some evidence to support clinical and experimental observations that proteolytic species of Clostridium may have an adjuvant action in gas gangrene.

The combined proteolytic reactions of several bacteria might be much more effective in causing septic decomposition of dead tissue than their individual reactions. Local gas in infected wounds may be ascribed to any of the vigorous saccharolytic or proteolytic enzymes of such organisms as Cl. perfringens, Clostridium aerofetidum and Cl. sporogenes. Such infections might be more pronounced with a mixture of bacteria capable of producing active gas-forming enzymes; indeed, even organisms normally regarded as saprophytes, such as Cl. tertium and Cl. sphenoides with their energetic saccharolytic powers, might contribute to the development and occurrence of gas in infected wounds.

This bacteriologic study was a time-consuming task beyond routine investigation. Primary anaerobic platings were incubated for from seven to fourteen days to enhance the isolation of slow growing bacteria such as B. melaninogenicum. Difficulties in the isolation of certain species of Clostridium from mixed cultures have been long recognized. Smith[15] reported that study of a single specimen of invaded muscle may not be adequate to reveal the presence of all "anaerobic bacteria." The establishment of pure cultures of the different bacteria was a tedious task because of spreading growth by Proteus and certain species of Clostridium even on plates with a 3 per cent agar medium and dry surfaces. On occasion even compact and well isolated colonies of Clostridium were mixed cultures. All the Clostridium cultures were replated as many as two to four times to make certain their purity. Animal inoculations prolonged the study of toxigenic clostridiums and those resembling toxin producers, i. e. Clostridium tetani. Delayed biochemical reactions such as slow proteolysis of some substrates by cultures of Cl. putrificum and certain anaerobic streptococci made their complete study incompatible with routine investigation. As stated previously, some of the bacteria, including Clostridium, undifferentiated and anaerobic streptococci and other cocci, could not be systematically classified. At present these facts and results eliminate rapid technics of isolation and identification of the mixed floras of war wounds. The submission of infected wound material to the laboratory for bacteriologic study appears to be impractical for routine diagnostic examination except in those instances in which it may be desirable to determine the presence or absence of specific etiologic agents.

Thus lines of demarcation of infection of wounds appear to be more practical clinically than bacteriologically. With the presence of certain bacteria the potentiality of various clinical entities exists, but the course, severity and final manifestation may in part be a function of the whole flora. To quote Waksman:[23]

"The physiology of an organism in pure cultures is so [illegible] from that of the same organism in a mixed population that one is often astonished to discover that an old friend, known and recognized by its specific reactions in given media, behaves quite differently in the presence of other organisms."

The sensitivities of the gram-positive bacteria to penicillin, the technics employed and the therapeutic effectiveness of penicillin have been described in the technical[3] and clinical[2] counterparts of this report. The use of penicillin against the polymicrobial infections emphasized its relative bacteriologic relationships. Since variation of sensitivity exists among strains and among species of susceptible bacteria, the efficacy of penicillin is dependent on the establishment of sufficient concentration levels in the blood in relation to the known in vitro sensitivity of a given organism. The fact that the strains of Streptococcus pyogenes, Cl. septicum and Cl. novyi were inhibited by 0.025 unit of penicillin per cc. of broth, the 7 strains of Cl. perfringens by 0.25 to 0.5 unit per cc. of broth and the 22 strains of Cl. sporogenes by 0.25 to 2.0 units per cc. of broth illustrates that with mixed infection of a wound the effective concentration of the drug may be determined by one of several pathogens present. Some strains of pathogenic species may tolerate amounts of penicillin beyond the present average blood levels,[24] as depicted by 2 strains of Staph. aureus which grew in 2.0 units per cc. of broth and the 4 strains of Cl. sporogenes which grew in 1.0 unit of the drug. Only when penicillin is chemically defined will it be possible to consider its effect in more absolute bacteriologic and clinical terms. It may be of some significance that both gradual and abrupt diminution of growth occurred with several species of bacteria in the various concentrations of the drug employed in testing their susceptibilities. For example, 4 of the 7 strains of Cl. perfringens revealed a decrease in growth two to three concentrations below the inhibitory concentration, while with the remaining 3 strains this decrease occurred one concentration below the inhibitory amount. In contrast 8 strains of Cl. sporogenes attained a heavy growth in concentrations up to the inhibiting amount, and the remaining 14 strains were partially inhibited one concentration below the inhibitory point. Any partial effect in vitro may be significant in vivo because with any antibiotic the normal defense mechanism still plays an important role in combating infections. At the same time, it is necessary to consider that limitation of dosages at critical levels may be a dangerous practice. Numerous investigators have demonstrated that penicillin-sensitive bacteria can be adapted to resist many times the original inhibitory concentration of the drug. With suboptimal concentrations in vivo the organism may be retarded in growth, but under certain conditions the tissue may not completely remove the infectious agent or may be relatively slow in its elimination. The dormant presence of the agent and its subsequent passage to another person might constitute its first phase of in vivo penicillin adaptation.

Lyons[11] has pointed out that wound infections are not controlled adequately without complete débridement and that devitalized tissues, such as muscle and sequestra, are not sterilized by penicillin. On the contrary, the culture of dead tissue removed by surgical methods following penicillin therapy may not infrequently duplicate the flora of initial cultures taken prior to the use of penicillin. According to Himes and White,[25] penicillin is not appreciably affected by serum, blood, pus, tissue extracts and autolysates, amino acids, carbohydrates, phospholipids and purines. Inactivation of penicillin by organisms such as coliform bacteria, aerobic spore-forming bacteria and certain species of Shigella presumably may occur through an enzyme.[26]

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. LYONS, DR. STEWART, DR. SNYDER AND DRS. RUSTIGIAN AND CIPRIANI

Dr. Hall G. Holder, San Diego, Calif.: It is generally recognized that no known chemotherapeutic agent will render open wounds sterile. The only sterile wound is the successfully closed wound. Thus the continued emphasis on delayed wound closure as early as it can be successfully accomplished. It has been possible to materially reduce the period of preparation of these wounds and obtain primary union on delayed suture by application of a mixture of urea, or carbamide, and one of the sulfonamide compounds. The rationale for employing this mixture is: (1) The known lytic action of urea on devitalized tissue without appreciable damage to normal tissue cells or the physiologic processes of wound repair. (2) Urea, because of its decided solvent action, was found to greatly increase the solubility of the sulfonamide compounds. Sulfanilamide was employed in the mixture because of its greater solubility. The proportions used were urea 87 per cent and sulfanilamide 13 per cent. The addition of 5 per cent pectin to this mixture materially reduces any cutaneous irritation resulting from the lytic action of urea on necrotic tissue. Infected wounds cannot be sterilized by any known antiseptic agent. It is more important to provide local tissue immunity with the removal of deterrents to wound healing by aiding the sequestration of necrotic tissue, rich in bacteria, by mechanical or chemical débridement and by adequate surgical drainage. This has been accomplished most expeditiously by the application of the urea mixture to suppurating wounds, thus materially reducing the time necessary to render them free from visible infections and ready for successful delayed closure. This in turn reduced to a minimum fibrosis and soft tissue dysfunction.

Dr. Emile Holman, San Francisco: I saw many wounds that had been treated with sulfanilamide at the front, and I am sure that many were not treated thoroughly. They were dusted superficially without any attempt being made to place the drug into the depths of the wound. In the last war it was found that modified Dakin's solution had to be introduced into all parts of the wound to be effective. I am sure that this is true of the local treatment with sulfanilamide. It must go into every nook and cranny of the wound.

Dr. Everett I. Evans, Richmond, Va.: If physicians had given more attention to the observation of clinical material and less to certain observations in the experimental laboratory, they never would have fallen for the idea that plasma is the agent of choice for the treatment of any type of true surgical shock. I think the general figure of about 40 to 50 per cent loss of whole blood in casualties, civilian and military, must be accepted, and that simply means what is brought out by Dr. Snyder, 2,000 or 3,000 cc. of whole blood replacement. I wince at the thought of any large scale surgical operation being contemplated or carried out without the preparation of at least six or eight transfusions. One practical point mentioned by Dr. Snyder is very important. It is the matter of recognizing concealed, continuing blood loss. One of the sorriest things I ever stated in the literature was how convinced I was of the importance of the local application of sulfonamides in burns. I wish it had never been put in print.

Col. Michael E. DeBakey, Medical Corps, United States Army: The observations I shall make in connection with this group of papers are based on rather broad statistical data collected in the Surgeon General's Office from various theaters of operation. In the first months of combat in World War II the incidence of gas gangrene was alarmingly high, but it became progressively lower as the war progressed and eventually was almost negligible. Plotted against time, it shows a fairly characteristic curve in all theaters, falling from an initial high of 3 per cent in some theaters to a final incidence of less than a tenth of 1 per cent, regardless of season or terrain or nutritional status or any of the other factors originally advanced to explain it. Experiences in the Third and Fifth Armies were characteristic; in the Fifth Army, for instance, in March 1945 there were only 9 cases of gas gangrene in the last 15,000 wounded. During the early days of the war when the incidence was highest, chemotherapy was employed religiously, both locally and systemically. Toward the end of combat, local chemotherapy was used little and in some armies was prohibited entirely. Penicillin, by that time in general use, had been employed in some campaigns and not in others, but whether or not it was used did not perceptibly affect the incidence of gas gangrene. The most rational explanation for the falling curve was everywhere the same; as the experience of surgeons increased, the surgical care of the wounded improved. Experiences in other types of infection support this theory, although statistical data to support it are not available. My second observation concerns the use of the new chemotherapeutic agent streptomycin and is based on experience derived from the Army streptomycin program. The studies included 179 cases of infected wounds, all combat-incurred, all with polymicrobial flora and most of them associated with chronic osteitis and fibrosis. Streptomycin was used in various systemic and topical combinations as part of the surgical management. Complete sterilization of the wound was rarely achieved, and only 40 per cent of the patients were regarded as improved; the remaining 60 per cent were definitely not benefited. The significant fact in the analysis is that almost without exception improvement was coincident with adequate wound revision, while the patients who failed to improve all seem to have had inadequate surgical intervention. The assumption seems justified that streptomycin deserves no more absolute reliance in the management of infected wounds than do other agents in the same or similar categories. Chemotherapy is no more than an adjunct in the surgical management of wounds, and the secret of good results is adherence to the fundamental surgical principles which have changed little since they were first advanced many years ago.

Dr. Frederick M. Allen, New York: Precise experiments distinguish the entities of hemorrhage, shock and infection, the fortuitous mixtures of which in clinical cases conduce to loose definitions and confused methods. Also the errors emanating from the Shock Commission of World War I were perpetuated disastrously in the recent war. Lives were lost in learning that plasma is unequal to whole blood; but though plasma is superior to isotonic solution of sodium chloride for hemorrhage, mention has not been made of the great life-saving value of isotonic solution of sodium chloride when blood or plasma is lacking. Shock must be conceived of as tissue injury which results in two processes, namely tissue edema and toxin formation. Any defense of the anachronistic plasma treatment by Army officers should be addressed to their scientific advisors whose amended instructions, issued after the German surrender, accepted the fact which I first demonstrated in 1939, that the predominant need is for large volumes of isotonic solution of sodium chloride to supply the demand of the tissues for sodium and water. The toxic factor in shock can be combated by only one method known at present, namely the reduction of temperature, while warmth is demonstrably fatal. Military surgery is said to follow the same principles as civil surgery. Local refrigeration should therefore be particularly demanded in war, when there are facilities in winter campaigns or in equipped hospitals or with an easily portable apparatus which was offered but not accepted. Burns were a numerous and fatal class of injuries, not treated with either salt solution or reduced temperature. The warming of shocked patients enlarges this list of wrong methods whose use unquestionably cost many lives and limbs. They are justly chargeable not to harassed Army officers but to their official advisors. If the value of the new methods for the treatment of war wounds is denied, it is remarkable that the Navy has reported benefits, and I await more complete publication of the extensive use of refrigeration in the South Pacific campaigns.

Dr. John D. Stewart, Buffalo: The problems of trauma encountered by the military surgeon are fundamentally the same as the problems of trauma met in civilian surgical practice. The civilian experience differs chiefly in intensity from that of the military surgeon. The causes of traumatic shock, its physiologic disturbances, the problems of wound management, the control of wound infection and the metabolic disturbances following a serious wound are no different in the battle casualty than in the seriously wounded civilian. There is a general tendency to disassociate experiences in wartime from those in civilian practice—a tendency which leads to a good deal of error and retards progress. I would like to make a plea that the surgeon take a comprehensive view of the severely wounded person. The surgeon must be concerned not only with the management of traumatic shock, the decision when to operate and what operation is to be performed, but he must be concerned also with the problems of after-care. A phrase has come into use in connection with military surgery, namely, the continuity of management of the wounded, which conveys a world of meaning. To delegate part of the treatment of the patient to someone else and to wait until notified that the patient is ready for operation, or to delegate the problems of after-care leads to less than optimal results. Here as elsewhere in surgical practice the direct, personal and continuous care of his patient is a responsibility which the well informed and able surgeon will cherish.

Dr. Champ Lyons, New Orleans: Dr. Holman has requested that we make this a little bit less of a "milk toast" affair, and he has leveled a fairly serious charge at me, that I am quoting ex cathedra evidence that local sulfonamide therapy is of no value. I knew the Navy was using local sulfonamide therapy; I read all about it in *Collier's* magazine. In the *Annals of Surgery*, over the past three years, there have been a long series of reports stemming from the National Research Council, an organization composed of a group that tried desperately hard to evaluate the role of chemotherapy. This was not strictly experimental work. It was controlled clinical observation. The conclusion, on several thousands of cases, was that the incidence of wound suppuration was increased by the local application of sulfonamide compounds. I think that is as close as one can come at the moment to a correct appraisal of the position of topical therapy.

Dr. Frank B. Berry, New York: I think all of us, mindful of World War I, believed that when we entered the northern European theater the incidence of clostridial infection would rise. Colonel deBakey put his finger on the reason why it did not rise. In this war we were blessed with a large group of superbly trained surgeons, the product of our residency system. Some had already had experience in warfare, some had had experience in warfare and civilian casualty surgical practice (those who were in England), and the newly arrived learned promptly. All were keenly aware of the indications for surgical intervention and of the necessity for the continuous treatment that Dr. Stewart has just mentioned. In our own army we required a monthly report on the incidence of clostridial infection and the names of the soldiers. Much to my amazement one month, in came a report of 7 cases occurring in a clearing station, with the soldiers discharged to duty with wet dressings. I investigated and found that this zeal on the part of the officer was due to the dissemination of information on clostridial infection. He had never seen a case in his life and was so afraid he was going to miss something that he was mistakenly reporting simple cellulitis of the feet as clostridial infection. Everybody was aware of the hazards and dangers of infection. I think the foremost reasons for the good results were this widespread dispersion of knowledge and the great number of good surgeons.

SUBTROCHANTERIC OSTEOTOMY IN POLIOMYELITIS

C. E. IRWIN, M.D.
Warm Springs, Ga.

Subtrochanteric osteotomy is a useful procedure in at least two conditions or deformities which may result from an attack of poliomyelitis: first, uncorrectable fixed pelvic obliquity, the obliquities which cannot be corrected by usual Soutter fasciotomies in combination with well leg traction apparatus and those for which Lowman's fascial transplant and Mayer's fascial stripping are ineffective; second, certain cases of severe gluteus medius weakness when it occurs on one side.

Before entering into the discussion of the faulty body mechanics in the presence of the two conditions mentioned, let us briefly review the action of the hip abductors and lateral trunk muscles in a normal individual under conditions of weight bearing.

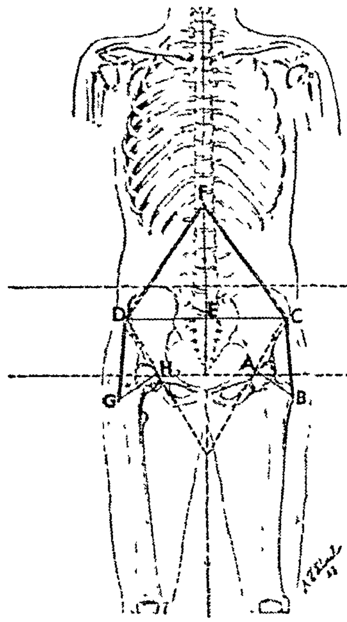

Fig. 1

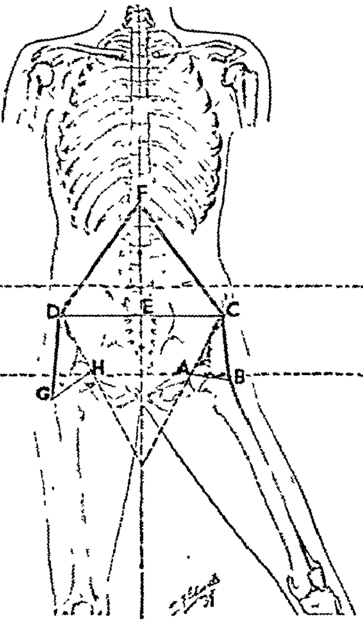

Fig. 2

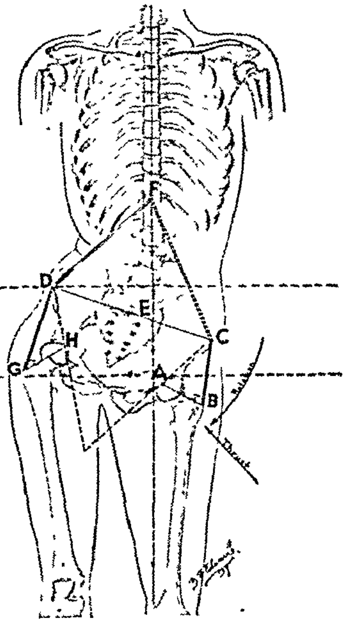

Fig. 3

Fig. 1.—A balanced skeleton. Notice the symmetry of the triangles above and below the iliac crests, the sides of which represent the lateral trunk and the hip abductor lever systems respectively.

Fig. 2.—A hip abduction contracture, represented by the double line *BC*. The pelvis is the fixed point from which the shortened abductors abduct the thigh. The deformity is localized.

Fig. 3.—When the abducted extremity, as shown in figure 2, swings into position for weight bearing, the femur becomes the long arm of a lever, pulling through the contracted abductors *BC* and forcing the pelvis down on the same side. In addition, a lateral thrust is transmitted through the head and the neck of the femur to the acetabulum, displacing the pelvis to the opposite side. There has been complete disruption of all lever systems and weight bearing thrusts concerned with locomotion.

Figure 1 represents a balanced skeleton in a normal person. For graphic illustration and as an aid in discussion, the affected muscle groups, the arms of the levers on which they act, together with the weight bearing thrusts, are represented by the sides of a triangle. Each triangle is made up of three components:

Below the pelvis: The double line *BC* represents the abductors of the hip. The single line *AB* corresponds to the arm of the lever through which the abductors exert their muscular effort. The broken line *AC* represents the weight thrust of the superstructure on the femoral head.

Above the pelvis: The double line *DF* represents the lateral trunk muscles. The single line *DE* indicates the arm of the lever through which the trunk muscles exert their effort. The line *FE* corresponds to the weight of the superstructure on the pelvis. Note the symmetry of the triangle above and below the pelvis in the normal balanced skeleton.

When a normal person takes a step, the pelvis is maintained at right angles to the vertical axis of the trunk by the action of the abductors pulling down on the pelvis on the weight bearing side. This effort is assisted by the lateral trunk group on the opposite side pulling up on the pelvis. The fulcrum, or pivoting point, is the femoral head on the weight bearing side. The femur on the weight bearing side is the fixed point from which the abductors pull down, and the rib cage and spine the fixed point from which the opposite lateral trunk groups pull up. The abductor lever system of the weight bearing side functions in conjunction with the lateral trunk lever system of the opposite side to keep the pelvis level when steps are being taken. The ribs and spine as the point of fixation for lateral trunk action are not as secure as is the femur as a point of fixation for the abductor muscle action. The ribs and the spine are dependent on the muscular efforts above the pelvis for fixation. For example, when the lateral trunk muscles *DF* elevate the pelvis, the spine is dependent on the lateral trunk muscles *FC* for counterfixation, and the lateral trunk muscles *FC* are, in turn, dependent on the hip abductors *BC* for their counterfixation. The femur on the weight bearing side then is ultimately the fixed point for this entire coordinated muscular function.

Any alteration in the strength of the muscles involved in this series of dependent or interdependent muscular efforts will disrupt the normal lever system and weight bearing thrust when a person takes a step. These facts will be referred to again in the discussion of severe gluteus medius weakness when it is present on one side.

From the Warm Springs Foundation.

Read before the Section on Orthopedic Surgery at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

DEVELOPMENT OF FIXED PELVIC OBLIQUITY

To emphasize the rationale of subtrochanteric osteotomy as a procedure to lessen the disability caused by fixed pelvic obliquity, it is well to describe the manner in which this deformity develops and to point out the faulty mechanics in its presence.

Having observed its formation from the earliest manifestations to the stage of final fixation with skeletal changes, I feel that the majority of them are initiated by contractures below the iliac crests and that few originate above this level as a result of inequality in the strength of the abdominal and lateral trunk muscle groups. There is only one type of true fixed pelvic obliquity. This type is present when the pelvis is held in a fixed oblique position by contractures both above and below the pelvis. If the pelvis is in an oblique position when there are no contractures below the iliac crests, its position is more properly classified as a scoliotic pelvis. It is no more than a part of the existing scoliosis.

Figure 2 represents an abduction contracture on the left side. The pelvis is the fixed point from which the shortened muscles *BC* abduct the thigh. If the extremities remained in this position the condition would be localized and no problem of widespread importance would result. This, however, does not follow. Obviously it is impossible for a person to walk with the extremities in this position. When the abducted extremity, as shown in figure 2, is brought into position for weight bearing (fig. 3), the femur becomes the long arm of the lever to force the pelvis down on the same side. The abductor group *BC* is rigidly contracted, and as the extremity swings through an arc to occupy a weight bearing position the pelvis and lower extremities move with it as a unit. In addition to the depression of one side of the pelvis, a lateral force or thrust is transmitted through the head and neck of the femur to the acetabulum, displacing the pelvis toward the opposite side.

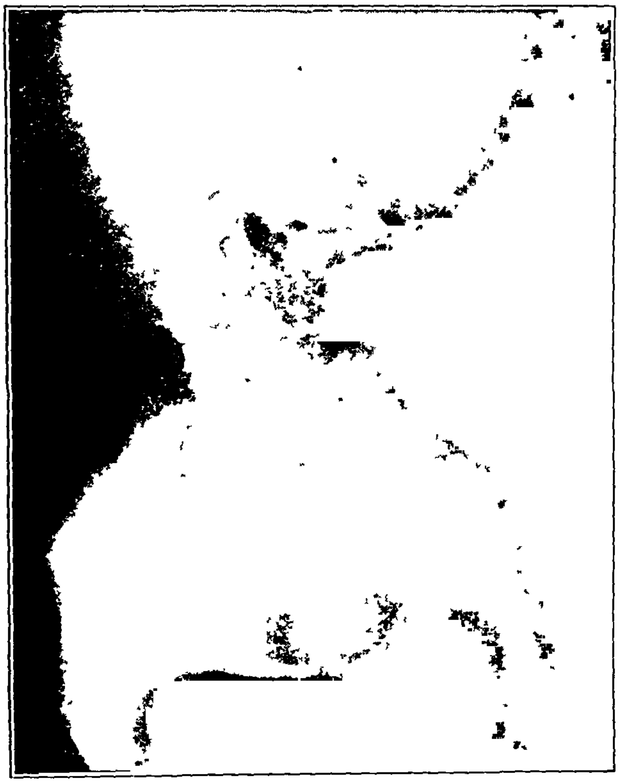

Fig. 4.—An uncorrectable fixed pelvic obliquity This patient's difficulty in walking is due to her inability to stand on the adducted extremity and get the opposite, or abducted, extremity forward to take a step

A complete change has occurred in the shape of the triangles above and below the pelvic level, with a resulting disruption of all the normal weight bearing lines and lever systems concerned in locomotion. Adaptive shortening of the lateral trunk muscles on the opposite side takes place secondarily to conform to the abnormal position of the pelvis. The pelvis is held in this oblique position by the two contralateral contractures until fixation with final skeletal changes develops.

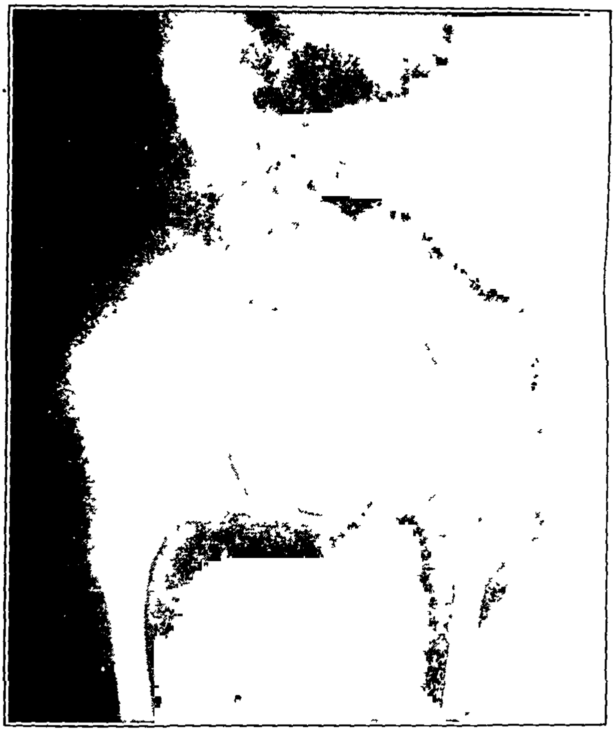

Fig 5.—Following subtrochanteric osteotomy it is possible to shift the abducted femur nearer the midline in a more efficient and useful position

The difficulty these persons have in walking is due to their inability to stand on the apparent short leg and get the opposite extremity forward to take a step. It is almost impossible for a person with this type of deformity to walk if he is wearing two long braces locked at the knee. If there is sufficient strength in the quadriceps of the apparent long side to allow the brace to be unlocked, flexing the knee will enable him to get this leg through to take a step, but the gait is rather unsightly and then has the appearance of an extremely short leg limp. The patient who is brace free on the apparent long side either widely abducts the extremity to get it forward or finally reaches the point of bearing all weight on the longer extremity, the opposite member dangling in flexion, adduction and external rotation of the hip, flexion of the knee and equinus of the foot.

At least six abnormal changes have taken place to cause this difficulty, three below the pelvis and three above the pelvis:

I. Below the Pelvis: 1. The femoral head on the side of the contracture has been depressed or lowered and shifted toward the midaxis of the body. The femoral head on the opposite side has been correspondingly elevated and displaced farther than normal away from the midline. An apparent difference in the length of the two extremities has occurred.

2. The extremity toward the side to which the pelvis has been displaced has remained in a weight bearing position. The abductors *GD* must be stretched out or elongated greater than normal length to allow this relation. Theoretically, the abductors *GD* must have elongated as much as the abductors *BD* have shortened. The efficiency or contractile strength of this muscle group, even if potentially normal, has been decreased

3. The pelvis has been rotated or displaced from its midline position under the superstructure. The line *FC*, representing the weight thrust of the upper part of the trunk, now passes almost over the femoral head of the apparent long side and at a much greater distance than normal from the femur of the elevated side. This has increased the demands of the work to be done by the abductors *DG*, which already have been weakened, having been stretched beyond their normal length. The apparent difference in the length of the two extremities plus the severe Trendelenburg when the patient is taking a step allows the pelvis on the opposite side to sag to an extremely low level.

II. Above the Pelvis: 1. The fixation point, represented by the ribs and lumbar vertebrae, from which the lateral trunk muscles *FC* normally elevate the pelvis, has been destroyed because of the abnormal elongation of the abductors *GD*.

2. The lateral trunk muscles *FC* have been stretched beyond their normal length, resulting in a decrease in their potential contractile strength.

3. The arm of the lateral trunk lever *EC*, through which this potentially weakened muscle group must now exert its effort, has been shortened.

These abnormal conditions above the pelvis make it impossible for the lateral trunk muscles *FC* to elevate the same side of the pelvis, which has already sagged to an abnormally low level

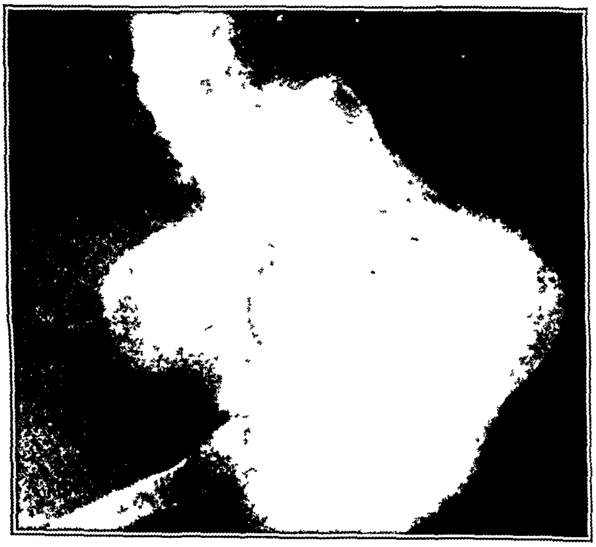

Fig 6—A severe fixed pelvic obliquity The spine has been fused with the pelvis in this position Note that the weight of the super structure falls in a plane lateral to both femoral heads

SEVERE GLUTEUS MEDIUS WEAKNESS

For all practical purposes we can say that essentially the same abnormal conditions as just described are present in severe hip abductor weakness. At the moment a person bears weight on this weak side to get the opposite extremity forward to take a step, the pelvis assumes an oblique position and the same abnormal mechanics exist above and below the pelvis. The oblique position of the pelvis, however, has been caused in a different manner. The pelvis has not been rotated and displaced from under the superstructure by contracted hip abductors It shifts away from its normal position over the center of the pelvis as the Trendelenburg becomes apparent. This shift of weight to one side helps to depress further the low side of the pelvis

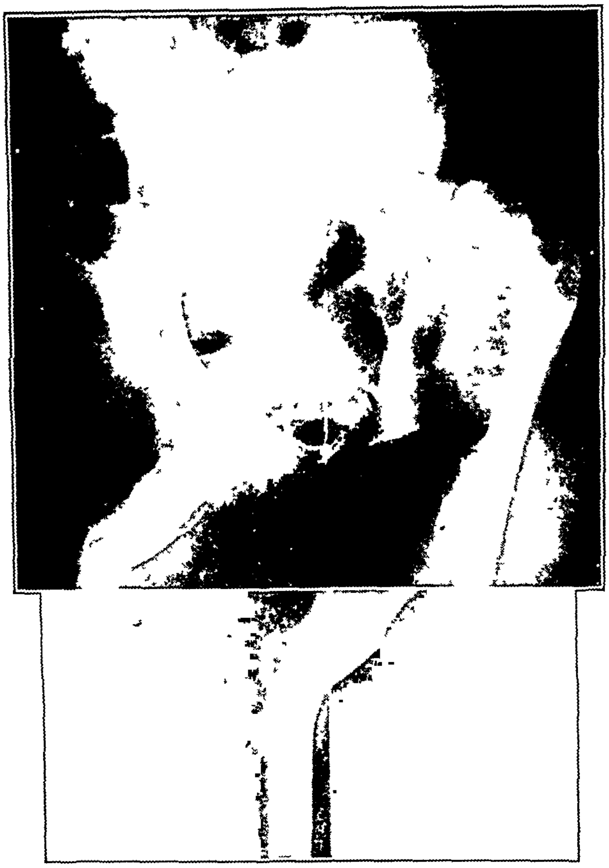

Fig 7—Osteotomy of the femur at the junction of the upper and middle thirds Anatomically the upper third of the femur is converted into femoral neck, and the shaft of the femur has been shifted into a position lateral to the weight of the superstructure

TREATMENT

Figure 4 represents an uncorrectable fixed pelvic obliquity. Since the pelvis in this case cannot be derotated or restored to a functional position under the trunk by any operative procedure, the alternative is to shift the adducted femur under the oblique pelvis nearer the center of gravity or weight thrust of the superstructure. Subtrochanteric osteotomy followed by adduction of the distal fragment permits a shifting toward the midline.

The operation does not correct the existing deformity (fig. 5). It does add actual length to an apparent short leg. The shift in the position of the femur decreases the work demanded of the abductors on the same side and the lateral trunk muscles on the opposite side. The severe Trendelenburg is decreased to the extent that these persons are made ambulatory provided they have sufficient strength in the upper extremities, shoulders and upper part of the trunk to use crutches.

Figure 6 represents the roentgenogram of an uncorrectable pelvic obliquity. Notice the extreme flexion and abduction contracture of the left hip. Unfortunately, the patient had undergone spine fusion elsewhere with the pelvis in this oblique position. The right hip is dislocated. The pelvis has rotated through an arc of almost 90 degrees. The weight thrust of the upper part of the trunk passes lateral to the left femoral head. Obviously the femur on the side of the dislocation or adducted side cannot be shifted toward the midline for more efficient weight bearing by a subtrochanteric osteotomy, as was done in the case represented in figure 5. In this second case the abducted femur was brought into a weight bearing position by an osteotomy done at the junction of the middle and upper thirds of the femoral shaft (fig. 7).

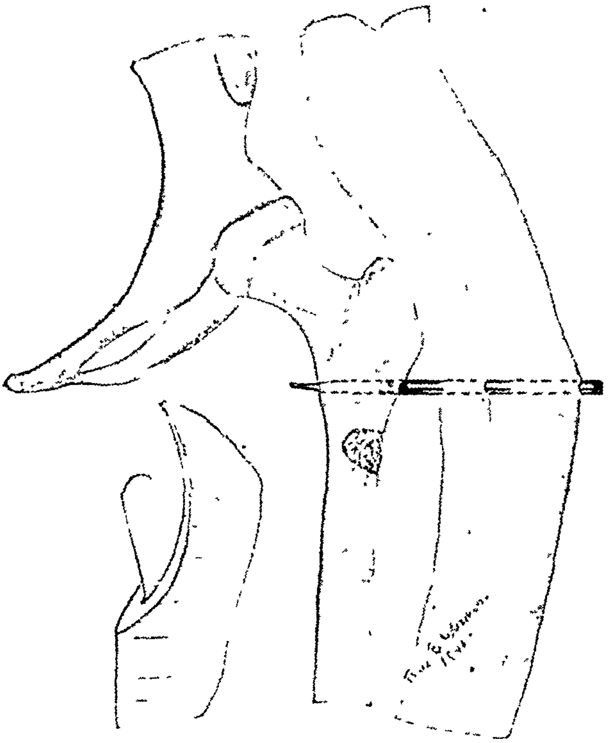

Fig. 8.—First stage of the osteotomy consists in removing a U shaped portion of bone just below the greater trochanter. The bone is cut up into chips and replaced in the recess. A Steinmann pin is inserted proximal to the osteotomy site, engaging both cortices.

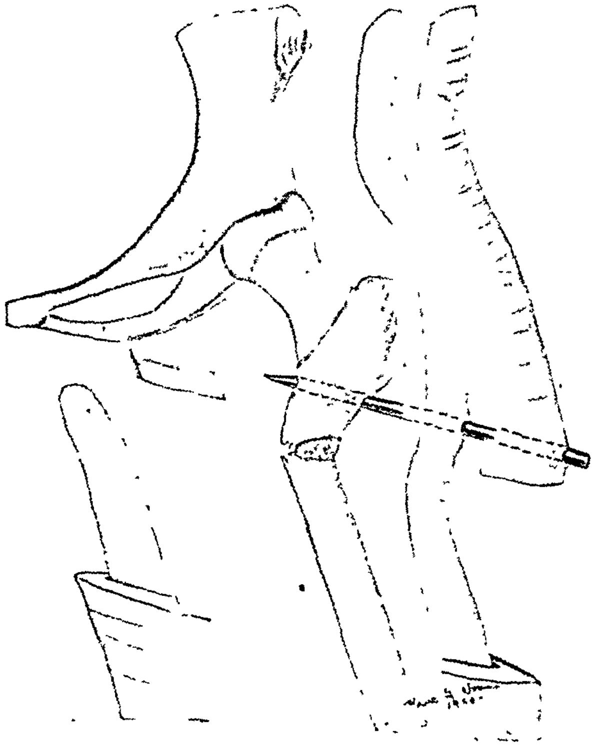

Fig. 9.—The osteotomy is completed four weeks later by manual osteoclasis. The newly formed callus around the bone shavings acts as a hinge. The proximal fragment is held in position by the Steinmann pin incorporated in the chest. At no time is there complete fracture.

The distal fragment was adducted, flexed and internally rotated. Anatomically the upper third of the femoral shaft was converted into femoral neck. The distal two thirds of the femoral shaft was shifted to the outside of the weight bearing thrust of the upper trunk. The pelvic obliquity has not been corrected.

After operation the patient could stand upright, bearing all her weight on the right lower extremity, the left being used only for balancing. She walked with two crutches, tripod fashion. She is now engaged in daily gainful occupation.

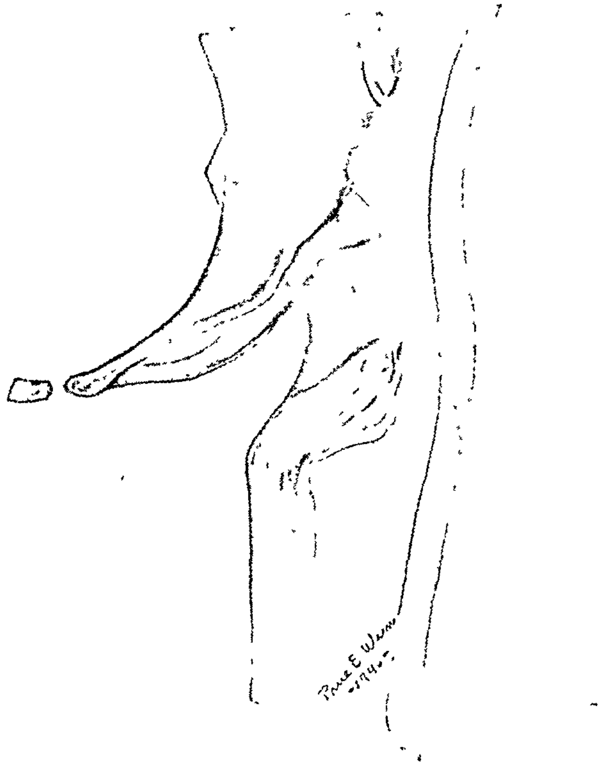

Fig. 10.—The Steinmann pin is removed at the end of six weeks. The osteotomy site is usually solidly fused at the end of eight or ten weeks.

TECHNIC OF OPERATION

One inch of the shaft of the femur in the subtrochanteric region is exposed (fig. 8). A Steinmann pin is inserted engaging both medial and lateral cortices proximal to the site of the proposed osteotomy. A U shaped portion of bone is removed from the femoral shaft including the lateral, anterior and posterior cortices. Three-eighths inch of the medial cortex is left intact. The portion of bone removed is cut up in small shavings and replaced in the recess. The incision is closed in layers. A double spica cast is applied incorporating the Steinmann pin. The osteotomy is not completed at the time of operation.

Four weeks postoperatively, with the patient under anesthesia, a wedge shaped portion of plaster is removed just below the pin with the base to the lateral side (fig. 9). The remaining medial cortex is fractured and the distal fragment abducted. Since the first procedure, sufficient callus has formed around the replaced bone shavings to prevent any displacement. At no time is there a complete separation of fragments. The osteotomy is completed by greenstick fracture, the new callus being used as a hinge. The proximal fragment is fixed by the Steinmann pin incorporated in the cast.

Six weeks postoperatively the Steinmann pin is removed and two weeks later sufficient callus has formed to allow removal of the cast. The entire procedure is completed within a period of eight weeks with practically no discomfort to the patient and a minimum amount of surgery and internal fixation (fig. 10).

COMMENT

In closing I would like to emphasize that an osteotomy should never be done in any case in which the pelvis can be restored to a functional position under the trunk by other procedures. It is indicated only in the uncorrectable fixed obliquities.

In severe unilateral gluteus medius weakness, the operation should be reserved for patients who cannot otherwise be made ambulatory.

ABSTRACT OF DISCUSSION

DR. CHARLES L. LOWMAN, Los Angeles: The positive Trendelenburg produced by the weakening of this important stabilizer tells the tale, and one sees the shifting and tilting of the pelvis described by Dr. Irwin. In the advanced cases of severe deformity such as he has described, we are confronted with what is probably one of the most vicious problems in orthopedics. The severe obliquity which the author describes in the patient who had had a spinal fusion is a tragic witness to the failure to analyze properly the imbalances of the pelvic and trunk muscles and anticipate the terrible deformities which impended. In these complicated cases the choice of the proper sequence of operative steps is very important. If the surgeon does not work out the kinetic imbalance in abdominal and pelvic musculature but sees only the structural spinal deformity and fuses the spine, he is quite likely after that not to be able to get a clear analysis of their action. The inability to carry out a series of bendings and twistings because of the fusion will interfere. The method of doing the partial osteotomy and waiting for callus formation seems a very wise procedure. In treating the patient whose pelvic deformity could not be changed but the adducted leg could be brought out parallel with the other in the weight bearing line so that the patient could get up, I think Dr. Irwin has shown considerable resourcefulness and surgical acumen in the face of a situation which most men would sidestep.

DR. J. WARREN WHITE, Greenville, S. C.: I wanted to get his ideas on it, and so I asked him to write this paper. He has handled a difficult subject well, and I for one have obtained a great deal out of it. There is one suggestion I should like to make that has helped me in working out some of these problems where it is so difficult to hold the apposition and the abduction alinement of the shaft of the femur. I have used the well leg traction in the way Dr. Hoke used it for years; that is a positive method of applying traction in abduction. It is in my opinion an ideal way of holding these extremities, and it really does hold them most securely. It puts the leg in position where the patient can use it to greatest advantage.

DR. C. E. IRWIN, Warm Springs, Ga.: The subject of this paper has been an extremely interesting problem to me, as I have worked on these deformities from their earliest manifestations to the stages of final fixation. The time allowed for this paper did not permit me to go into the operating correction of these deformities in the earlier stages. Those of us who see these cases comparatively early after the acute attacks should never allow deformities such as I have shown today to develop, but we shall occasionally find cases in which we shall find this procedure to be useful.

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association and Hygeia, the Health Magazine
Chicago

(Continued from page 178)

(NOTE.—*Following is the twelfth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 12. *The Journal Is Born*

1880-1884

1880

NEW YORK CITY

The session of the American Medical Association in 1880 was to prove as the years passed among the most significant of its meetings, except perhaps that of 1847 in which it was established and that of 1901 when it was reorganized. The significance of the 1880 session lies in the fact that it gave birth to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Until THE JOURNAL was established, the minutes of the meetings of the Association and such papers presented at its meetings as were able to survive the censorship of the Committee on Publication were printed in an annual volume of Transactions. These volumes were frequently late in their appearance, insufficiently edited and poorly published. Dr. S. D. Gross, following his visit to the meeting of the British Medical Association, had suggested that the Transactions be discontinued and that a periodical be published, to be known as the American Medical Association Journal. A resolution was passed at the meeting in Washington in 1870 but was immediately reconsidered. Nine years later Dr. S. E. Chaillé of New Orleans read a paper on more efficient organization of the Association in which he urged a change in the method of publishing the Transactions of the Association, but that suggestion was not followed. Then in his presidential address in New York in 1880 Dr. Lewis A. Sayre devoted himself to the needs of the American Medical Association and again considered the publication of the Transactions. He recognized the frequent complaints, the excessive costs, the delays in publication and the fact that the papers often had previously appeared in various medical journals of the country.

"It is very questionable," he said, "whether the mode pursued by the British Medical Association, in establishing their own journal, would not be an immense improvement on our present method. The British journal is the exclusive property of the association; and by the liberal compensation of an accomplished editor, a weekly edition is issued, instead of an annual volume."

Dr. Sayre traced the growth of the *British Medical Journal,* the decision by that organization to publish its regular journal, and the conspicuous progress that the British Medical Association had made once its journal was established. The increase in membership of the British Medical Association was definitely credited to its periodical. He pointed out not only that the British journal had become a powerful means of attracting new members to the association and of keeping them in it by maintaining their interest in connection with the association and "giving them value for their money" but that its advertising columns contributed largely to increase the funds of the British Medical Association, bringing in an income at that time of something like $25,000 a year. He pointed out that the British Medical Association had been able to carry on many activities through the profits made by its publication and that after all expenses were paid there remained an annual surplus of from $3,000 to $5,000 which had been accumulated in a reserve fund. In his consideration of the operation of the *British Medical Journal* he emphasized that not all the papers read at an annual meeting were published, but full discretion was given to the editor to publish or not according to his estimate of the importance and interest of the papers to the members at large. Indeed, Dr. Sayre said that this method included the germs of an association peculiarly adapted to American ideas. "It is essentially democratic and entirely representative. It is dependent for its success on the intelligence, union, and good will of the members. . . . Above all, it is a most successful and influential means of increasing the membership, enlarging the power and widening the basis of the association and of making it a living organism during the intervals between the annual meetings."

With unusual insight Dr. Sayre declared that "the success of the *British Medical Journal* has been largely dependent on the manner in which it has been conducted. The weekly *Journal* did little for the association until it fell into the hands of an experienced editor, whose ability is so generally recognized that there is no need to dwell upon it, and to whom a large and unfettered responsibility is left, although he remains, of course, personally responsible to the executives of the association for the right use of the power entrusted to him, as every editor does to those who appoint him. It will be necessary to find for any organ which this association may publish an editor of recognized position, whom the association would accept as its worthy officer and representative in so responsible a post, a man of literary skill, scientific knowledge and journalistic experience or, at least, journalistic instincts and tact."

This discussion, together with some reference to the metric system and to current accomplishments of American surgery, constituted most of the presidential address of Dr. Lewis A. Sayre. When the address was delivered, a vote of thanks was tendered to the President for his able address. On motion of Dr. William Brodie of Michigan a copy was requested for publication, and his recommendations were referred to a committee of five with instructions to report at the same meeting.

On the first day of the session Dr. Foster Pratt of Michigan presented a report on the suggestions that had been made at the previous session by Dr. S. E. Chaillé of Louisiana, one of which concerned the substitution of a periodical medical journal for the annual volume of Transactions. Most of the report of the Pratt committee dealt with the recommendation that the Association refuse to recognize state societies which did not provide for and encourage the organization of county societies. The Pratt committee did not favor this suggestion. Other proposals concerned the status of members of various types. One proposal urged every medical college to give a lecture or lectures to each graduating class on the importance of medical organization to the profession and the people. The committee felt that a resolution to this effect could do no harm and might do some good, but it pointed out also that the Association had delivered itself from all control of and all responsibility for medical schools and it questioned the propriety or dignity of volunteering advice where it could not compel observance.

As to the publication of a periodical, they felt "it is a consummation devoutly to be wished" and "probably a very large majority of intelligent medical men will unhesitatingly declare in favor of the periodical—*if* (and they italicize the *if*) it can be properly established and maintained." They urged patience in making progress and they expressed their belief that the "safest and surest way to attain most of the desirable ends proposed is to patiently wait the operations of the law of growth." The distinguished committee that made this report included Foster Pratt, N. S. Davis, S. D. Gross and A. N. Bell. This report, on motion of Dr. William Brodie, was accepted and ordered to be entered on the minutes.

On the third day of the session a resolution was offered by Dr. J. R. Bronson of Massachusetts requesting the appointment of a committee of five to report on the following morning on the practicability of formulating all of the proceedings in journalistic form as recommended by the President in his annual address. This resolution was unanimously adopted.

The President of the Association appointed Drs. J. R. Bronson of Massachusetts, W. W. Dawson of Ohio, W. H. Pancoast of Pennsylvania, N. C. Husted of New York and J. S. Green of New Jersey as a committee for formulating the proceedings in journalistic form.[1]

As the session ended, Dr. J. R. Bronson, serving as chairman of the committee to consider publication of the Transactions in periodical form, made the following report:

> The committee appointed to consider the practicability of formulating all the proceedings of this Association in journalistic form find on approaching the subject that its merits are such as to warrant the belief that the medical profession as a whole, upon due consideration, will heartily endorse the radical change proposed, in that it will enable the profession aforesaid to

---

[1] A history of The Journal of the American Medical Association published June 3, 1899 in The Journal through error gives the names of the committee which was appointed to pass on the recommendations in the president's address. That committee included Drs. John H. Packard, S. D. Gross, J. S. Weatherby, E. S. Dunster and Walter R. Gillette.

> commence to utilize at an early day the valuable contributions to the literature of this Association. The details necessarily incident to the change proposed are too important and too numerous to be compassed within the period given the committee to report. We desire, therefore, to report progress.

A motion was made to lay this on the table, but the motion was lost. Then Dr. William Brodie moved that it be accepted and the committee was continued.

At this session the Section on Practice of Medicine had a report on a diet cure of rheumatism which, it is there claimed, was successful, and a rather extensive report on the Salisbury plan in consumption by Dr. Ephraim Cutter of Boston, a method which involved removing a yeast which was supposed to cause tuberculosis from the blood and tissues by starving it out. The yeast apparently fed on starches and sugars and the diet planned to eliminate starches and sugars as much as possible.

Great progress was being made in the Section on State Medicine, which was urging the establishment of state boards of health and of a national board of health. In the membership of this section one finds such names as those of John Shaw Billings and Abraham Jacobi. Dr. John Shaw Billings traced the growth of the movement for a national board of health, recognizing the part played by the American Public Health Association and other groups.

There were proposals for the establishment of a nomenclature and for an adequate census of the population. There was a forward looking paper on the physician in education dealing with the question of the physician to the schools.

1881

RICHMOND, VA.

Early in the meeting at Richmond, Va., in 1881 a report was presented by Dr. Joseph H. Warren of Massachusetts of a trip he had taken abroad in which he referred again with great praise to the *British Medical Journal* and to its editor, Mr. Earnest Hart, who, "by his great push and enterprise, has caused the journal to outrank any other journal published by any other medical association." He pointed out that the *British Medical Journal* had brought into contact with that association the best men in the British medical profession and, he continued; "I would, Mr. President and Fellows, that the American Medical Association had, in place of its ponderous annual publication, a weekly journal published under its own immediate auspices; and I would that at its head we had an editor with a vigor equal to that of Mr. Hart, that he might, with his editorial staff, stir all the dry and moldering members into a new life, and that he might infuse into them an interest and activity equal to or even greater than that which the British Medical Association shows today."

On the second day of the session Dr. John H. Packard of Pennsylvania read the report on journalizing the Transactions and submitted a resolution that a committee of five be appointed whose duty it should be to digest and report in detail as early as possible a plan for the publication of a weekly journal by the Association, the nomination of an editor, his salary, and the time and place of publication of such a journal. On motion of Dr. N. S. Davis this resolution was amended to leave out the nomination of the editor. Next a motion was offered that the secretary and treasurer be added to the committee and then another resolution urged that the members of the previous committee attending the session be added to the new committee. The committee appointed included Drs. John H. Packard, N. S. Davis, John Shaw Billings, Lewis A. Sayre and R. Beverly Cole, with the treasurer and the secretary.

By this time it was becoming apparent to the meeting of the American Medical Association that the system of appointing delegates from the state and county medical societies and from similar groups was not working satisfactorily. Members continued to urge the development of county medical societies as constituents of state medical societies and to suggest changes in the Constitution and By-Laws to make the Association more definitely a representative body.

The committee which had been trying to get a hearing before the Congress on better social recognition for the medical officers reported that it had arrived in Washington but found the Congress too much preoccupied with "some contested election cases to make any new enterprises probable of success." Besides, the committee had concluded that the resolution did not cover sufficient ground to include all the needed legislation and that the best thing to do was to wait for another session of the Association.

The address of the President, Dr. John T. Hodgen, dealt with the qualifications of surgeons as specialists and with various surgical contingencies.

Unusual in the printed Transactions was a paper on thumb sucking, involving the application of a cuff over the elbow to keep the child from reaching the mouth. In this astute manuscript the author said that thumb sucking is more disastrous to the child than sucking the other fingers because the thumb, once in the mouth, remains there more easily during sleep.

The report of the committee on journalizing the Transactions, signed by Drs. Packard, Gross, Weatherly, Dunster and Gillette, considered various technics for publication of the Transactions of the Association and compared the costs of a periodical with the publication of an annual volume of transactions:

> The great aim of the movement would be to furnish the Association with an organ—an exponent of its principles, a medium of communication between it and its members, between the members themselves and between the Association and the profession at large. The columns of this journal should be open to all respectable contributors. It should be controlled by no clique, free from personalities, high in tone; discriminating, but not prejudiced; independent, but not erratic. All this—and nothing less will warrant any hope of success—implies the securing of the most able editorship. It would be necessary also to provide for the employment of one or more assistant editors, and for the payment of contributors.
>
> Beyond all doubt a weekly, properly conducted, would far better meet the requirements of the case than either a monthly or a quarterly journal; but the labor of editing it would also be much greater. Should the Association resolve to undertake this enterprise, the question of form would be a most important one.

The committee indicated that the method of collecting dues was undependable as a source of income; it felt that there must be regular annual dues. It had obtained from the treasurer of the Association a complete statement of its income and they suggested that each member receive THE JOURNAL in response to the payment of dues. The committee quoted at length from the presidential address of Dr. Sayre as to the factors which should govern the publication of a periodical and the choice of an editor, and it summarized by recommending the publication of the periodical according to the plans that had been mentioned.

1882

ST. PAUL

The first business of the Association at the meeting in St. Paul in 1882 was a battle over the admission of delegates from New York. Most of the state medical societies of the South and Middle West and that of Pennsylvania protested the admission of delegates from the state of New York. All these protests were referred to the Judicial Council. The difficulty lay in the fact that the New York State Medical Society had passed a resolution which was alleged to ignore the Code of Ethics.

The difficulties with New York had to do with the distinctions between allopathists and homeopathists.

Dr. N. S. Davis presented a resolution in behalf of the Women's National Christian Temperance Union.

Then came the report of the committee on journalizing the Transactions, which was so vital to the Association that it was made a special order for the Thursday morning session.

Resolutions continued to be offered from various states condemning any attempts to adopt unusual methods of practice. A new section had been formed, known as the Section on Dental and Oral Surgery.

The report of the committee on publication was signed by Drs. John H. Packard, N. S. Davis, L. A. Sayre, J. S. Billings, R. B. Cole, W. B. Atkinson (the secretary) and R. J. Dunglison (the treasurer). This report estimated the cost of printing THE JOURNAL at about $15,000 a year. It indicated that the annual receipts varied from $2,000 to $6,000 and it felt that changes in the plan of the organization by which the doors of the Association could be opened to all members of the state and county societies on application were imperative. According to a recent census there were some 90,000 physicians in the United States. It was thought that, if 3,000 of these should become members of the Association, the mere expenses of THE JOURNAL would be provided for. The committee also considered the methods by which the business part of the enterprise could be properly carried on. It gave thought to the possibility of selecting an experienced business manager but seemed to prefer the idea of entering into a contract with some well known and responsible publishing house to issue THE JOURNAL for it. In this connection the committee felt that it might be necessary to incorporate the Association so as to give it a substantial character. It gave thought particularly to the appointment of an editor, saying:

> Upon the selection of a suitable man will hinge, in a very great measure, the success of the whole enterprise. He must be possessed of intellectual ability, firmness, tact and judgment; free from partisanship, of high professional and moral tone, and of such standing as will enable him to attract the support and secure the influence of the best class of contributors.
>
> It is very desirable that the editor's relation to the Association should be such as to leave him, as far as may be, untrammeled, while still responsible for the due discharge of his functions; that the arrangement should be such as to make it worth while for a suitable man to accept the position and still to preserve for the Association a just and equitable control of it. There would be obvious difficulties in the way of an election by the whole body annually, and it seems to us that the matter can hardly be placed to advantage in the hands of any of the existing committees.

THE BOARD OF TRUSTEES

With extraordinary wisdom the committee proposed that there should be elected by the Association a Board of Trustees—nine in number—to serve for three year terms and that the appointment of an editor be placed in the hands of these trustees. To the editor it assigned the appointment of assistant editors and on the Board of Trustees it placed responsibility for the conduct of the financial aspects of the publication. The committee recommended that the name of the journal should be THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and that outside subscribers be charged $6 a year for their subscriptions. It indicated, moreover, the method by which subscribers were to be secured.

Following the presentation of this report, Dr. N. S. Davis offered some resolutions, which were seconded by Dr. William Brodie of Michigan and unanimously adopted, making effective the recommendations of the committee.

EXPERT WITNESSES

The question of expert witnesses had also begun to be agitated in the annual session of the Association. A resolution had been offered to the effect that it was "the sense of the American Medical Association that it will be conducive to justice and to the dignity of the profession if medical expert testimony can be presented to the courts without the appearance of bias or influence from either side of the case and simply as a straightforward statement of scientific facts."

PERMANENT SECRETARY AND WASHINGTON

There had apparently begun to be some agitation also against the office of permanent secretary, and a resolution was offered and set by for a year that the nominating committee hereafter annually nominate a secretary who would serve without compensation.

Dr. Davis again offered a resolution requesting that every second meeting of the Association be held in Washington.

THE JUDICIAL COUNCIL

Most of the problems before the Judicial Council related to representatives of homeopathic groups in the Association. After carefully examining the documents relating to the New York State Medical Society, the Judicial Council adopted unanimously the following opinion:

> Having carefully examined the Code of Ethics adopted by the New York State Medical Society at its annual meeting in February 1882 (as furnished by the secretary of said society), the Judicial Council find in said code provisions essentially different from, and in conflict with, the Code of Ethics of this Association; and therefore, in accordance with the provisions of the Ninth By-Law of the American Medical Association, they unanimously decide that said New York State Medical Society is not entitled to representation by delegates in this Association.

The Judicial Council also dropped from membership a number of other physicians on protests from their state medical societies.

THE LIBRARY

Although little has been said in these annual summaries of the work of the Association about the library, which was slowly accumulating in Washington, the librarian reported year after year. The report for 1882 indicates that the library now contained 1,702 distinct titles with about 4,448 volumes, inclusive of pamphlets. The Association was purchasing a good many foreign periodicals and books, subscribing $50 a year to the *Index Medicus* (which needed the help) and making a great many exchanges with the foreign publications.

THE VICE PRESIDENT ACTS

This was the first meeting of the American Medical Association in which the Vice President was compelled to substitute for the president. The task was undertaken by Dr. P. O. Hooper, the First Vice President. He paid gracious tribute to Dr. N. S. Davis, to whom more than to any other one individual the American Medical Association owed its founding and its development. He praised the work of the Association and recorded its success, and he welcomed the establishment of a periodical as a landmark in its progress. Particularly did he exalt the Principles of Ethics, urging the body not to retreat, not to involve itself in a world of inconsistencies. "The broad laws of demarcation between the irregular and the true physician should never be obliterated."

THE BOARD OF TRUSTEES

On the last day of the annual session of 1882 the committee on nominations suggested the following members for the first Board of Trustees of the American Medical Association to serve three years: Drs. N. S. Davis, E. M. Moore and J. M. Toner; for two years, H. F. Campbell, J. H. Packard and L. Connor; for one year, P. O. Hooper, A. Garcelon and L. S. McMurtry. This was adopted.

1883

CLEVELAND; THE FIRST EDITOR

At the meeting in Cleveland in 1883 Dr. N. S. Davis, chairman of the Board, reported that 2,100 pledges to sustain THE JOURNAL had been received from a mailing of 40,000, thus assuring its publication. Estimates for printing had been obtained, and as the bid of a Chicago company was lowest Chicago was recommended as the place of publication. The Trustees were authorized to proceed with the publication of THE JOURNAL. Dr. N. S. Davis was then introduced to the Association as the editor-in-chief and made some remarks. A vote of thanks was tendered to Dr. Davis for his willingness to assume the burdensome duties.

The original intention was to issue the first number of THE JOURNAL on July 1, but owing to the publisher's lack of facilities for such publication the first number of THE JOURNAL did not appear until July 14, 1883. It contained in its thirty-two pages a complete transcript of the minutes of the meeting of the Association. This was a clear gain of ten months on the usual time of appearance of the Transactions. The periodical also contained a number of scientific articles, some medical news and some notes of correspondence. It was printed by A. J. Newell at 71 and 73 Randolph Street. There is a preliminary note quoting the Transactions of the Association for 1851 which reads "The American Medical Association, though formally accepting and publishing the reports of the various standing committees (and sections), holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except otherwise decided by special resolution."

The Transactions of the Association as they appear in this first issue of THE JOURNAL represent a notable advance over previous Transactions in at least two particulars. They are more complete, and the various subjects discussed are introduced with suitable headings so as to make reference easy.

The first Board of Trustees adopted certain principles which deserve repetition. For instance, the editor was asked to secure as far as practicable the services of reliable correspondents in each of the great medical centers of the country and some of those in Europe. He was asked to maintain correspondence with the secretaries or proper officers of state medical societies. He was asked to solicit "advertisements from all medical educational institutions and hospitals open for clinical instruction, from book publishers, pharmaceutists, instrument makers, and all other legitimate business interests. But all advertisements of *proprietary, trade mark,* copyrighted or patented medicines should be excluded. Neither should any advertisements be admitted with one or more names of members of the profession as indorsers, having their *official titles* or *positions* attached.

"In other words, no advertisements should be admitted which fairly contravene in letter or in spirit the principles of the national code of ethics."

A special committee was established to nominate trustees to take the place of those whose terms had expired. This committee stated that the following were selected to complete the Board: Dr. Alonzo Garcelon of Maine, Dr. P. O. Hooper of Arkansas, Dr. L. S. McMurtry of Kentucky and Dr. J. H. Hollister of Illinois.

At this session the Association took action on a resolution urging the establishment of nurses' training schools in every county in the nation. It was proposed to form a special section on psychologic medicine. A resolution to revise the Principles of Ethics was laid on the table.

The address of the President of the Association, Dr. John L. Atlee of Lancaster, Pa., was devoted largely to reminiscences to some of the distinguished teachers of the past, including Dr. Caspar Wistar, Dr. Nathaniel Chapman, Dr. Philip Syng Physick and Dr. George McClellan. He had been a classmate of Dr. Isaac Hays, editor of the *American Journal of the Medical Sciences,* and he referred to him as "one who has done more for American medical journalism than any other physician in the country."

The first issue of THE JOURNAL in which the Transactions and the address of the President are published includes also a paper on "Tonsillotomy Without Haemorrhage" by W. C. Jarvis of New York and one by Harry Gradle of Chicago on "The Treatment of Otorrhoea with Antispetic Powders." There is another paper on plastic surgery involving restoration of a lost cheek by a flap from the shoulder, written by Dr. Edmund Andrews of Chicago. There is an editorial on the change from the Transactions to a periodical and information to the effect that an index to the Transactions of the Association from its beginning to 1883 had been prepared by the permanent secretary. There is a request for exchanges and the hope that publishers would send one copy to the Library in Washington and another to THE JOURNAL.

Rather amusing is a communication from Philadelphia telling of the excitement caused there by the appearance of the new publication. Philadelphians "hope that THE JOURNAL will be truly national in character." Interesting also is a letter to the editor from Washington, D. C., proposing the formation of an insurance company to provide benefits for widows and orphans of physicians. Some news notes with reference to transactions of various societies complete that issue.

The second issue of THE JOURNAL contains the proceedings of the American Association of Medical Editors which was held in Cleveland, June 5, 1883. Dr. N. S. Davis was the president of that organization and he delivered an address on the present status and future tendencies of the medical profession in the United States. At the conclusion of the medical editors' meeting on June 5 that association adopted a resolution recommending Dr. N. S. Davis of Chicago to the American Medical Association as being the most suitable editor for THE JOURNAL which they shortly proposed publishing. The address by Dr. Davis on the present status of the medical profession reviewed in detail the manner in which the American Medical Association came into being as a representative body interested largely in improving the standards of medical education. He was desirous that more physicians associate themselves with organizations in the states and counties. He felt the need of specific research on definite problems.

"It is this want," he said, "of definite, well devised plans of original investigation and inquiry on the one hand, and of well planned cooperative observations on the other, that has led many of the wisest and most learned among us to think that all our medical organizations, whether state or national, amount to little more than a means of making professional acquaintance, enjoying annual seasons of social intercourse with each other, highly gratifying in their nature but accomplishing little in the advancement of medical science."

He deprecated the interest in specialization, saying "In the brief period of less than fifty years we have specialties in almost every part or region in the human body." And he was concerned with the restless desire for privileges to advertise these specialties more liberally than the general code of ethics adopted by the American Medical Association would permit. He saw already a tendency to disintegrate the national organization through special interests and influences. Dr. Davis emphasized the laws that had been passed in the various states following the establishment of the American Medical Association to protect the public:

> It has appeared from the review of the past that, during the first twenty-five years of our national existence, laws were enacted in nearly all the then existing states designed to protect the people from the impositions of ignorant and designing men claiming power to heal the sick, by prohibiting unlicensed practice, etc.; but which were nearly all repealed or so amended as to render them inoperative during the next thirty years by means of popular prejudices and false representations attendant upon the rise and spread of Thompsonianism and homoeopathy; the one playing upon the mind of the masses with all the power of bold and ignorant empiricism, and the other captivating the credulous tendencies of the more fashionable circles by a mystic transcendentalism inclosed in sugar pellets. The first has died a natural death, leaving a sickly offspring bearing the name of eclectics, while the second, like some medicines, retains its name as a "trade mark," and its organization for political influence, while its once transcendental vagaries have long since practically ceased to exert an influence over the treatment of disease.

Reviewing the status of the profession, he found some 60,000 to 70,000 persons, more or less educated, engaged in the alleviation of human suffering, with many voluntary society organizations for the mutual improvement of its members, all centering in one representative national organization—the American Medical Association. He found the education of the profession in the hands of sixty or seventy independent medical schools with the influence of their rivalry perverted by the recognition of their diplomas as equivalent to a license to practice. He deprecated the long absence of any adequate laws for protecting the people from the imposition of and ignorance of medical pretenders, but he saw great gain in the establishment of national and state boards of health and regulating the laws for the practice of medicine in several of the states. These legislative tendencies, he felt, would determine the status of the profession for the next fifty years.

MEDICAL ADVERTISING

Later issues of THE JOURNAL included a Chicago letter and a Boston letter, but by the issue of July 28, 1883 there began to be some protests against the advertisements. Witness the following delightful document from Burlington, Iowa:

> *Dear Doctor:*—I have received your first number and am delighted with it as a journal; but I am not so pleased with your advertisements. Parke, Davis & Co. have bored the physicians of the Northwest sufficiently with their ready-made prescriptions. In fact, they have taken the place of Ayer's Pectoral and Humbold's Buchu and are patronized by all the quacks and all the patent medicine men in this country. Soon I presume you will advertise Warner's safe cure for kidney trouble. Now, I protest right here against the organ of the American Medical Association being the means of disseminating any such advertisements. I ask a place for this in your correspondent's column, and see if I am not indorsed by nine tenths of the physicians in the land.

PROGRESS OF THE JOURNAL

A little later there is a Cincinnati letter and it begins to be apparent that the weekly journal is serving a most useful purpose. The medical progession has found in THE JOURNAL a voice. Physicians begin to express their opinions of new discoveries and of social changes. The papers read at the sections at the meeting in Cleveland are being published within a month or two of their reading. Speeding up of report intensifies the speed of progress. There are discussions in the correspondence columns of contract practice and medical ethics, of the question of consulting with irregulars, and more and more protests against the exploitation of the medical profession by the venders of "patent" and proprietary medicines.

The issue for Oct. 27, 1883 actually contains a paper read before the American Academy of Medicine on Oct. 9, 1883. It is entitled "Is It Fair?" and it is a study of the comparative political position of the medical profession in the United States.

Toward the end of the volume there are letters from Indianapolis and from Washington, D. C. The final number for the year indicates that 3,000 or 4,000 copies are being published each week and that it has been a considerable burden on the printers. A title page and an index are provided and the editor offers to make good missing numbers to any subscriber, to any person who wants to have a complete file for the year. The editor had also arranged to secure letters from Paris, of which two were published in the volume; one was published from London.

1884

WASHINGTON, D. C.

THE JOURNAL continued on its even course. During the first months of 1884 it began to provide fields of interest to the medical profession introduced in Washington; but apparently the editor was having some difficulties in filling his pages, for he began to republish from other periodicals and he included a good many trivia in his pages. His correspondent from Burlington, Iowa, who signed himself with the initials E. H. H., continued to trouble the editor with his letters about the advertising, being now annoyed by the advertisements of medical institutions, which were apparently somewhat profuse in their descriptions of the physicians who conducted these institutions.

THE NEW YORK STATE MEDICAL SOCIETY

An important editorial appeared in the issue for Feb. 9, 1884 discussing the action relative to the New York State Medical Society that had taken place in Cleveland. The editorial asked "Was the New York State Medical Society extruded from membership in the American Medical Association, or did she take herself out by her own act?" Apparently some of the New York delegates were a little disturbed by the situation and were proposing a reconciliation. The reconciliation was to be on the basis that the Association would thereafter recognize as a delegate any licensed physician from the state which sent him.

In the issue for Feb. 23, 1884 there was a discussion of a proposed resolution from St. Louis asking the Association to deny representation to medical colleges which paraded the names of the professor in their circulars. The editor called attention to the fact that the Association had not had any representatives from medical colleges for a dozen or fifteen years. This gave the editor opportunity to discuss still further the questions raised by the representative from New York State who proposed the reconciliation. But the New York correspondent did not take this lying down. His letter in the issue for February 23 began with the statement that the editorial confirmed his statement, "if any confirmation was needed," that the American Medical Association was in the grasp of a few men, and the writer ended with this paragraph:

> Your statements only confirm those of my former letter in showing that, however cunningly the machinery of the American Medical Association may have been devised in the interests of harmony, it certainly is not, in its plan of working, entitled to the name of "American" and must undergo material change.

By this time a writer from Buffalo had decided that the argument was sufficiently good to permit him to take a hand, and his letter also was duly published.

MEDICAL EDUCATION

The issue for April 5, 1884 had an excellent editorial on medical colleges and their endowments which ended with the significant statement that "it is not new colleges that is [sic] required but a more efficient management of old ones."

The address of the President, Dr. Austin Flint, for 1884 appeared in the issue for May 10, 1884. It was a review of the history of the Association, with increasing emphasis on the necessity for high scholarship among those who wish to be physicians, and it came to its end with the paragraph "The practical question is 'What can the Association do to promote more and more the elevation of the standard of medical education?'" He did not accept the charge that medical education in the United States was unworthy of any commendation and as contemptible when contrasted with the educational advantages of other countries. He found advantages in the American methods of teaching. He defended the medical schools against the charge of venality and deception and he set up a program for elevating the standard of medical education, utilizing the forces of the American Medical Association. Here, for the first time, is the suggestion of a standing committee on medical education designed to secure uniform action with reference to requirements for matriculation and for graduation.

THE PRINCIPLES OF ETHICS

An equal portion of Dr. Flint's address was concerned with the Code of Ethics; he discussed the new code—so called—in the state of New York which would permit consultations with all legally qualified practitioners of medicine. His argument was legalistic and he was inclined to believe that the New York code could be accepted, since that code defined an irregular practitioner as one whose practice was based on an exclusive dogma to the rejection of the accumulated experience of the profession. He emphasized that the needs of the patient are always to be the first consideration and he approved that, except in extreme emergencies, consultation with quacks, charlatans and irregular practitioners can only injure humanity.

Here we find the address of the President and also of the chairman of the Section on the Practice of Medicine appearing in THE JOURNAL at the very week of the meeting.

The editorial for May 17 was an obituary notice of S. D. Gross, followed by a report in editorial form of the thirty-fifth anniversary meeting of the American Medical Association. The meeting was held in Washington. More than 1,200 regularly registered members were present. The papers had been well chosen, and there was some condemnation of the Section on State Medicine for having only a few papers and those not especially well selected. In his address, Dr. Austin Flint had paid tribute to Dr. S. D. Gross, who had died at the very hour when the address was being delivered.

ANIMAL EXPERIMENTATION

For the first time the Association found it necessary to adopt a resolution in defense of animal experimentation. A committee of seven was appointed, to be known as the Committee on Experimental Medicine, charged with the duty of opposing, by all legitimate means, unwise or ill considered legislation. This battle against the forces of ignorance and fanaticism had gone on and on with the victory never permanently won, so that year after year in many of our states, in many of our large cities and even in the Congress of the United States it becomes necessary to defend the use of animals in experimentation for the advancement of medical science and the improvement of human health.

THE JOURNAL

The report of the Board of Trustees which appeared in this volume pointed out that the regulation relative to advertisements established at the Cleveland meeting was a wise restraint tending to elevate the dignity of THE JOURNAL but at the same time deprive it of a considerable revenue.

The publication of THE JOURNAL had brought about a remarkable increase in the income of the Association. The Association found itself with a surplus in the treasury over all expenses. In the editor's report to the Board of Trustees he pointed out that he had been compelled to reject a good deal of advertising on account of the restrictions.

Having made an excellent report, Dr. Davis had offered the Trustees his resignation. The Board, with but one dissenting voice, requested Dr. Davis to withdraw his letter of resignation. In a letter of response he was impelled "now to yield to your nearly unanimous request that I withdraw the resignation tendered" but he stated definitely that he must positively withdraw from a position involving so much labor and responsibility at the end of the next year.

A minority report was presented by Dr. John H. Packard. Dr. Packard pointed out that the Association was able to have a surplus because the editor abstained from drawing his salary and that the board was counting on his abstaining from drawing his salary for some time to come. However, this was not his chief complaint. He felt that THE JOURNAL had not, in his opinion, approached anywhere near the standard of what the organ of the associated medical profession of the United States should be. He felt that publication of THE JOURNAL in Chicago was difficult because there was not sufficient access to large libraries. He felt that contributions to its pages should be properly and liberally paid for. He did not like the printing. He thought that the resignation of Dr. Davis should be accepted and that the publication office of THE JOURNAL should be transferred to some Eastern city, preferably Washington, Philadelphia or New York. The minority report was first called for and it was laid on the table by 191 ayes to 74 noes. The majority report was then adopted.

DIFFICULTIES AND DISTURBANCES

There were other points of difference which now began to be discussed in the House of Delegates. There were many resolutions recommending changes in the Principles of Ethics. It was proposed that the Section on Ophthalmology, Otology, Laryngology and Rhinology be divided into two sections, one dealing with ophthalmology and the other with otology, laryngology and rhinology. There was even a resolution calling attention to the fact that the American Medical Association was composed of all nationalities, denominations, sects and creeds, and that many of its members were skeptics and materialists and that therefore the custom of opening the sessions of the American Medical Association with a prayer should be abolished. This motion was unanimously rejected.

Congress was urged to make proper preparations for the Medical Library and Museum. There was a resolution, well in advance of its time, asking Congress and the legislatures of the several states to label lye, a caustic potash, as poisonous. It took about fifty years for Congress to act on that one, and it required the work of Chevalier Jackson in our time to make the Congress realize the necessity.

In his editorial presenting the Transactions, Nathan Smith Davis proposed several excellent technics for registration at the annual sessions. He pointed out that the effectiveness of the sections depends on the permanence and efficiency of their secretaries and he recommended greater permanence in this office.

One is constantly amazed at the remarkable talent for organizational efficiency and the supreme qualities of leadership manifested by Nathan Smith Davis in the first forty years of the work of the American Medical Association. If ever it could be said that one man more than any other deserved credit for having inspired the necessary cooperation for advancement, for having manifested ingenuity of thought and action, for having worked with indomitable courage and energy for the advancement of an organization, that credit should go to Dr. Nathan Smith Davis.

The first issue of THE JOURNAL for June 1884 contained a paper by Leartus Connor on the "American Medical Association of the Future." He found that there had been 509 medical periodicals in the United States up to that time, of which 136 were surviving and 373 departed. He analyzed the forces which prevailed toward the inauguration of such journals and their continuance. "THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION," he said, "is now passing through the first stages of a similar development under less favorable circumstances. Like its English brother, it has already been subjected to sharp criticism, it has had to meet the envy, jealousy and disappointed ambition of disappointed persons and localities, but we have no doubt that in the end it will surmount all these obstacles and have a future even more brilliant than its English brother."

He concluded with the suggestion of some general principles along which medical journals must move. He felt that a medical editor, like a poet, is born and not made and that he must be given freedom in his work. He was certain that the most influential medical journals would develop in the great commercial centers and that with increasing wealth and power they would be able to pay their editors such salaries that they could devote all their time to the profession of medical journalism. The medical journals of the future would be more and more separated from medical colleges, medical societies or other corporate bodies that cripple their perfect independence to work and think and speak for the great masses of the medical profession. "The advertising claims of the medical journal of the future," he said, "will have less and less influence over the utterances of the editorial pages" and, further, that the advertising columns of the best medical journals of the future "will contain a notice of nothing which shall not be free to every pharmacist to manufacture, as free as the formulas of the Pharmacopeia." He felt that the medical journals would be able to pay more for the contributions to their pages as well as to their editors. And, finally, he was convinced that experience would do most of the teaching. "The past shows," he said, "that it is impossible to persuade a man that he is unfit to run a medical journal until he has convinced himself by trying."

In the issue for June 28, 1884 N. S. Davis made some comments on the completion of his second volume. He admitted that there had been some imperfection in his work, but he was willing that the numbers issued during the last three or four months should be compared with reference to all that related to style of publication with the best weekly medical publications in this country. He was a little burned by some criticisms from the *New York Medical Journal,* which in one issue had published half a column of corrections of its own typographical errors; and he called attention to a few mistakes that he had found in the *Record,* "whose editor is so fond of criticizing others." Dr. Davis was smarting over the criticisms from the East and he said "Had either of these blunders occurred in THE JOURNAL or any other outside of 'one of the great *Eastern* cities' it would have been held up as a sample of incompetent provincial work for the next six months." *(To be continued)*

Clinical Notes, Suggestions and New Instruments

HABITUATION TO MEPERIDINE HYDROCHLORIDE (DEMEROL HYDROCHLORIDE)

JOHN J. CURRY, M.D.
Boston

The problem concerning the liability of addiction to meperidine hydrochloride (Demerol Hydrochloride) has attracted renewed interest because of recent publicity concerning the drug in the lay press. While numerous reports (Batterman[1] and others[2]), some of them extensive, have appeared dealing with the clinical use of meperidine hydrochloride, it will probably require considerable time before detailed information concerning the extent of habituation and addiction is collected. At present it appears that since euphoria may occur following the use of the drug, certain persons are likely to become habituated, especially if it is administered over a prolonged period. However, in many instances difficulty has not been experienced in discontinuing the medicament after it has been prescribed for several months.

When meperidine hydrochloride was freely administered to one group and given in therapeutic amounts to another group of confirmed morphine addicts true addiction resulted, but the duration of physical dependence produced was considerably shorter than that with morphine.[3] It was concluded that meperidine hydrochloride possessed addictive liability but that with clinical doses the addictive liability of the drug was less than that of morphine.

Clinicians who have had extensive experience with meperidine hydrochloride have concluded that for routine use the addictive liability is minimal and certainly less than that with morphine. In the continental literature it has been noted[2] that several cases of addiction in severely psychopathic persons or former morphine addicts have been described. In this country only 1 case of spontaneous addiction to meperidine hydrochloride is reported[4] and this patient had been addicted previously to Pantopon (the total alkaloids of opium as soluble hydrochloride) and habituated to dihydromorphinone hydrochloride and barbiturate. In this case the estimated dosage of meperidine hydrochloride was in the range of 600 mg. a day. Cases of addiction following its ordinary therapeutic use have not to my knowledge been described. Anslinger,[5] however, has stated that the files of the Narcotic Bureau contain numerous cases of addiction involving the use of this drug. It is not clear whether or not these are cases of primary addiction.

The case of a young, highly intelligent patient who was familiar with drugs and their reactions and who ingested considerable quantities of meperidine hydrochloride by mouth over an extended period is recorded. Unfortunately, six months elapsed before details of the episode were elicited. The ingestion of large amounts of the drug was confirmed by a member of his family and a friend.

REPORT OF CASE

A white man aged 32, married, was seen because of malaise and mild epigastric cramps. About one year prior to this visit his regular physician had prescribed meperidine hydrochloride for similar symptoms. The administration by mouth of 100 mg. of the drug twice a day resulted in relief of symptoms and a definite sense of well-being. He continued the medicament as prescribed for a three week period, until the euphoria began to disappear and the cramps reappeared. At this time, of his own accord and chiefly to recapture this sense of well-being, the dosage was increased to 150 mg. twice a day. For about one week the euphoria returned, and he then also experienced a sensation of dryness in the mouth. The amount of the medicament was then increased to 250 mg. twice a day, again with a return of the feeling of euphoria. In addition, he began to experience anorexia with an increased sensation of warmth and sweating. This dosage of 250 mg. twice a day was continued for approximately one month, and at the end of this period there was a loss in weight of 15 pounds (7 Kg.). In the following four week period it was necessary to increase the amount of drug ingested to 250 mg. three times a day in order to maintain his euphoria, and an increasing number of symptoms developed. Shortly after he took the meperidine hydrochloride there was an increased alertness and his performance of work was exceptionally good. Two to three hours later, however, there was an intense desire for the medicament, associated with a loss of self confidence.

At this time he frequently became irritable, and his temper was occasionally out of control. Slight excitement would cause facial pallor and tremors of the entire body. As far as he could recollect, there was a lack of notable change in the size of the pupils.

He smoked an increased number of cigarets but did not take alcoholic beverages. Anorexia continued and further loss of weight ensued. Nausea and vomiting did not appear. Thirst was extreme and persisted despite the ingestion of large quantities of water and from 1 to 3 quarts of milk a day. There had been a gradual onset of constipation, so that a dry, hard movement occurred at from three to five day intervals. Despite the increased intake of water the desire to urinate was absent during the day, but on reclining at night there occurred a sudden intense desire, which was repeated four to five times within an hour and on each occasion resulted in a copious output of urine. Sweating also appeared more prominently at night.

He began to awake from sleep occasionally with a sudden start but did not have any unusual dreams that he could recall. In the morning there was increased difficulty in rousing himself, and he felt mentally sluggish. A tic of the right eyelid developed and muscular tremors appeared which occurred chiefly in the lower extremities. Palpitation of the heart occasionally was noted but was never bothersome.

About the end of this month euphoria disappeared, and with the appearance of increased irritability the dosage was again raised to 300 or 350 mg. three times a day. A fleeting sense of well-being returned, and he continued to maintain a keen interest in his work. Anorexia persisted but there was still an absence of nausea or vomiting, and bowel habits remained unchanged. Nocturia increased to eight or nine times with sharp urgency. Insomnia began to appear but did not disturb him to any extent. Meperidine hydrochloride was not taken after midnight. Muscular tremors recurred more frequently, especially if he suddenly moved after sitting in a relaxed position. Actual shaking of legs and thighs took place and was relieved in four to five minutes by walking about. Headaches, dizziness or visual disturbances were not observed. At the end of a month on the above dosage, in an unsuccessful attempt to regain some degree of euphoria the dosage was increased to 1,250 mg. a day. The drug now caused increased irritability and nervousness, and he became disgusted with his predicament. After about one week on this increased dosage he fell on two occasions and finally collapsed in the bathroom. He was admitted to a local hospital for a period of seven days, and during that time he was asymptomatic and had no desire for the drug. For three days after discharge from the hospital a slight desire reappeared, and on the third day he took 100 mg. every two hours for five doses. Euphoria reappeared, but he became dyspneic and felt dizzy and faint. The medicament was discontinued and has been avoided since.

COMMENT

It appears remarkable that such a large quantity of meperidine hydrochloride was ingested over a period of about seventeen weeks and its use then discontinued with so little difficulty. Craving for the drug was absent while the patient was hospitalized and physical signs or symptoms did not appear when it was discontinued. Between the seventh and the tenth day after the drug was stopped a mild desire for it reappeared. At this time he again took some meperidine hydrochloride but such undesirable reactions occurred that the drug was again discontinued. It would appear, then, that in this patient habituation developed becase of the sense of well-being induced by the meperidine hydrochloride. While in some instances it is difficult to be sure that physical dependence is not established, the lack of signs and symptoms in this case after the drug was discontinued would seem to indicate that true addiction was not produced.

SUMMARY

A patient aged 32 ingested about 72 Gm. of meperidine hydrochloride (Demerol Hydrochloride) over a period of approximately seventeen weeks. Because of the occurrence of euphoria, habituation resulted, but true addiction apparently did not develop.

APPARATUS FOR THE CONTROL OF VAGINAL URINARY INCONTINENCE DUE TO FISTULAS

MARIO A. CASTALLO, M.D.
Philadelphia

Uncontrolled urinary seepage from the vagina due to fistulas is a source of discomfort and irritation. Since a vesicovaginal fistula in many instances cannot be repaired in the acute stages, weeks and months must elapse before an attempt at closure is made. During the interim the patient's vulva and perineum become excoriated.

The apparatus employed to obviate the discomforts accompanying urinary fistulas consists of a vaginal diaphragm fitted to the patient for size and a mushroom catheter (fig. 1 *A*). A small opening is made in the diaphragm, the upper portion of the mushroom catheter is cut off (fig. 1 *B*), and the resultant flange on the catheter is glued to the inner side of the diaphragm, with the type of glue commonly used in all operating rooms to repair rubber gloves (fig. 1 *C*). The proper size diaphragm is ascertained and placed in the vagina as in figure 2. The catheter is connected by rubber tubing to a drainage bottle at the side of the bed.

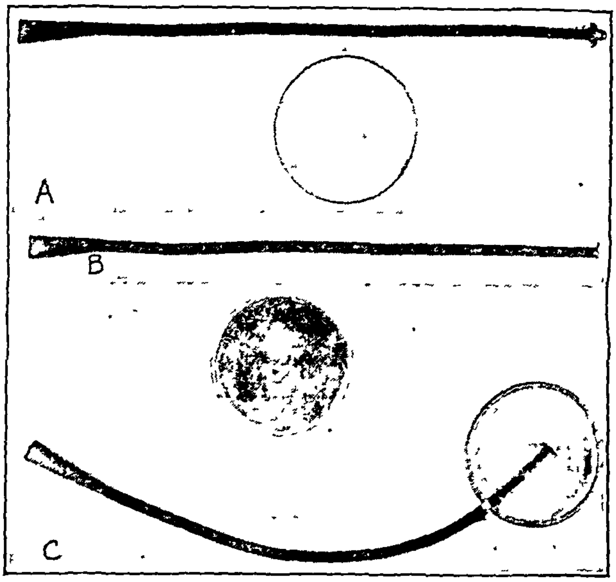

Fig. 1 *A*.—Mushroom catheter and vaginal diaphragm. *B*, upper portion of catheter is cut off. *C*, resultant flange is glued to the inner side of the diaphragm.

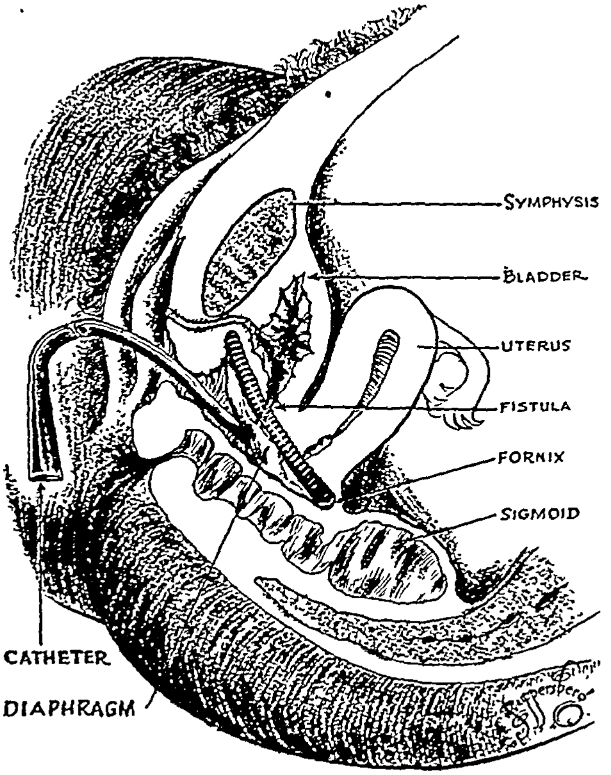

Fig. 2.—Diaphragm in the vagina.

The apparatus has been used now for over two months by a bedridden patient at the Jefferson Medical College Hospital, and it has been a source of great comfort to the patient and has made nursing care easier. A no. 75 diaphragm was used while the patient was in bed. After the patient became ambulatory a no. 80 diaphragm proved more efficacious. While the patient is on her feet the catheter is connected to a small baby-sized hot water bottle strapped to the patient's leg, allowing the patient her usual freedom.

1621 Spruce Street.

Council on Foods and Nutrition

The Council on Foods and Nutrition has authorized publication of the following article. It consists of portions of a paper entitled "Basic Research Needs from the Viewpoint of a Pediatrician" and read in Washington, D. C., before a joint meeting of the Scientific Advisory Committee and the Food Industries Advisory Committee, the Nutrition Foundation, April 4, 1946. James R. Wilson, M.D., *Secretary.*

SOME BASIC RESEARCH NEEDS IN NUTRITION

PHILIP C. JEANS, M.D.
Iowa City

If one were to ask various physicians their concept of basic research, each would give a different reply, a reply dependent on individual special interest. It is generally in the field of his special interest that a person sees most clearly the borders of information and the specific needs for data.

Evidence is accumulating that good nutrition is highly effective in preventing recurrences of rheumatic fever. More evidence is needed as to the exact role that nutrition plays. If good nutrition is effective in preventing recurrences, no doubt it is also useful in preventing the initial attack.

More information is needed concerning the relationship of nutrition not only to rheumatic fever but to resistance against infections in general. Experiments with animals repeatedly have shown a relationship, but they have not shown the specific factors or the mechanisms, nor has the application of this evidence to human beings been proved. Nutrition during growth is of paramount importance to the pediatrician. The unanswered questions are legion. One needs more information in regard to the factors which affect fetal nutrition and development; such knowledge should help to reduce the infant mortality rate. More should be known of the composition of the body during various stages of growth. This knowledge would be of great aid in determining dietary requirements.

Of special interest to the pediatrician are the relative biologic values of human and cow's milk. It is known that babies fed human milk have a vastly different body composition than those fed cow's milk. The baby given cow's milk has more protein and mineral and less water. Which composition is preferable, if either? Is human milk protein superior to that of cow's milk? At present there is no satisfactory method to determine the value of a protein in that it is not known how to construct an experimental diet to exclude the influence of unidentified factors. Other protein problems are of importance. There is need for better methods for estimating the amino acids in foods. The bioassays used are not yet specific. Along with knowledge of amino acid content of foods the amino acid requirements must be known. Such information would be of great aid in assessing and prescribing diets and of special importance in successful intravenous feeding, a phase of medical management now coming into prominence. Often circumstances arise in which intravenous alimentation becomes necessary. The methods are not yet wholly satisfactory. While the nitrogen requirements are being met fairly well, the energy needs of the body offer greater difficulties in that an excess of sugar is required. Suitable preparations of fat and methods of administering them would solve much of this problem, and apparently the solution is just around the corner.

Intravenous alimentation is closely linked with the formation of body proteins, particularly those of the blood. More must be learned concerning the factors affecting the formation of blood proteins—factors affecting the rate of formation and those that determine their normal level. Such knowledge would not only be of advantage in promoting better understanding of normal body processes, but it would be of greatest assistance in treating those chronic diseases in childhood, such as nephrosis, in which the blood proteins are consistently low and are restored to normal with the greatest difficulty.

While dietary requirements and recommended allowances have been set up with good nutritional authority behind them, it is recognized that the actual requirement of few of the nutritional essentials is known with accuracy. Perhaps a few unknown vitamins exist, but among those that are known the role of several in human nutrition is not yet determined. Of the two common varieties of vitamin D (vitamins D_2 and D_3) the relative value in human nutrition has not been determined with finality; this information is of much more than academic interest. Of the various periods of life that have been studied from a nutritional standpoint the most neglected has been that during the prepuberal growth increase and adolescence. The few studies that are recorded indicate a need for more extented and intensive observations. While physicians may consider that they are fairly well informed concerning the nutritional requirements of those in health, they are definitely lacking in information as to the requirements as affected by disease. I believe this group is aware of the difficulties confronting those who wish to make surveys for the purpose of detecting subclinical nutritional deficiencies. Special types of examination are required, and some of the criteria used are not wholly diagnostic of a single deficiency. Search for better diagnostic methods is needed. Knowledge of the dietary requirement for fat by the human being is inadequate. Fats serve several useful purposes, among them the making of food more palatable. Certain fatty acids have been designated as essential, but the experimental observations leading to this designation were made with animals. There are no data that show a human requirement for fat of any variety. Diets extremely low in fat have been fed successfully to children over periods of years, but no one has fed a fat-free diet. Much has been written of the superiority of butter fat over vegetable fats for animals, but no one has shown such a relationship for the human subject. Babies have been reared successfully with diets containing only vegetable fats, but the exact conditions of the experiments with animals were not duplicated.

One of the most controversial subjects of interest to the pediatrician is dental caries. Until some general agreement as to cause can be reached, research must continue. Each person consulted will have his own particular concepts as to the direction the research should take. One of the most widely held views is that dental caries is caused by the bacterial decomposition of fermentable carbohydrates in the mouth. Is it not strange that no one has ever tried the experiment of giving extra sugar to children whose diet is otherwise adequate and complete? In the isolated instances in which this has been done, control of caries was accomplished. A large scale experiment is needed. It is possible that the statement that sugar causes dental caries is comparable to a statement that rice causes beriberi. The Council on Dental Therapeutics of the American Dental Association does not accept advertising to the effect that vitamin D and calcium have any function in preventing dental caries after the teeth are fully formed and erupted. It would seem relatively easy to prove or disprove this point, and such a project should be undertaken in a manner more thoroughly controlled than in the past.

It is my own concept that the factors protective against dental caries are numerous and interrelated. In almost none of the recorded experiments have the subjects and the diets been closely controlled to the extent that only one variable was operating. I believe that the best type of experiment is one in which the subjects receive a fully adequate diet with the exception of the single factor being studied. Furthermore, each subject should be supervised at each meal and between meals in order to know that the prescribed diet is ingested. A good reason why this type of controlled study has not been carried out on a large scale is that it is difficult and expensive; yet, it should be done. Investigators have carried out this type of procedure on a small scale, but on such a scale the results are too slowly accumulated. Orphanages are commonly used for studies of groups of children. These institutions are inadequate because of the lack of cooperation by the administrative personnel and the difficulty of complete regimentation without such cooperation. While the subjects must be completely regimented, it is necessary at the same time to supply facilities for physical, educational, emotional, social and recreational normality of life. The conditions must be such that the lives of the children will be none the worse because of their employment for study.

CHRONIC RELAPSING PANCREATITIS

Diseases in the upper part of the abdomen with pain are difficult to diagnose. Among this group is chronic relapsing pancreatitis, characterized by recurring attacks of pain in the upper part of the abdomen, sometimes associated with disturbances in function of acinar and islet cells of the pancreas and by certain sequelae. These include principally steatorrhea, diabetes and calcification. The disturbances in function are transient and mild at first, but they may later become permanent.

Comfort and his co-workers[1] believe that the disease is not uncommon and that occasional reports in the past of cases of chronic pancreatitis do not represent its true incidence. Twenty-nine cases were selected from a larger series on the basis that the pancreatitis was the sole cause of the abdominal symptoms and that it was recurrent and chronic.

The causes were not discovered. A history of long alcoholism antedated the clinical onset in some instances. Alcohol and dietary indiscretions appeared to precipitate some of the acute attacks. The disease made its first appearance at ages from 10 to 66 years, with the mean at 38 years. It was commoner in men than in women, unlike cholecystic disease. It was also without predilection for the obese.

The attacks of pain were characteristically severe, steady and prolonged. The pain most often gradually increased in severity, reached a plateau and then gradually declined. Such a cycle required from two to thirty-five days, although some were shorter. The intervals between attacks varied from a few hours to six years. The seizures of pain required opiates, which did not terminate the attacks, so that repeated injections were usually necessary. Other symptoms were chills, fever of a moderate degree, diarrhea, nausea, emeses, jaundice and constipation.

The physical manifestations were not fully determined, because few patients were seen during an attack. However, loss of weight, fever, jaundice, shock, tenderness and muscle spasm, epigastric mass, hepatomegaly and splenomegaly were sometimes seen. Some of the findings persisted in the intervals between seizures. Laboratory examinations revealed at times such conditions as slight anemia, albuminuria, glycosuria, elevation of blood urea, hyperglycemia, abnormal glucose tolerance, elevated serum bilirubin, elevated serum amylase and lipase, increased blood sedimentation rate and steatorrhea.

The pathologic changes in the pancreas were determined by examination at operation, by microscopic study of seven surgical specimens and by examination at necropsy in 3 cases. They varied from edema, inflammation, hemorrhagic necrosis and abscess in the acute phase to atrophy, fibrosis, cyst formation, calcification and stone in the late stages. The pathologic changes tended to persist and progress in the intervals between recurrent clinical manifestations. The essential pathologic process may be, the authors believe, either repeated attacks of acute interstitial pancreatitis, repeated sublethal attacks of so-called acute hemorrhagic pancreatitis or a combination of the two. The cysts were pseudocysts and were regarded as encapsulated areas of hemorrhagic necrosis. The stones may have caused the pancreatitis in some cases, but the sequence of events was believed to be more commonly the reverse.

The diagnosis was established from the history and physical examination alone in typical cases. Tests of pancreatic function and x-ray demonstration of calcification proved the existence of disease of the pancreas and aided in the diagnosis, especially in otherwise questionable cases. After pancreatitis was established, its primary nature in the pancreas was proved by the exclusion of diseases of the liver and biliary tract or other organs capable of producing pancreatitis. The history alone plus exclusion of diseases capable of simulating pancreatitis was sometimes sufficient to establish the diagnosis. The diagnosis was easier during acute attacks than during remissions.

In the differential diagnosis disease of the biliary tract, especially biliary colic, must be excluded. Hydronephrosis, perforated duodenal ulcer, intermittent intestinal obstruction and heart disease must be excluded by the history and by laboratory tests. Carcinoma of the pancreas or the ampulla of Vater may cause pancreatitis which at first resembles primary chronic pancreatitis, but carcinoma is progressive. Retroperitoneal tumors and nontropical sprue must also be excluded, the latter especially in the presence of steatorrhea.

The course of the disease was characteristically that of recurring acute exacerbations separated by short or long intervals of relative clinical quiescence. The summation of anatomic changes, which at first were demonstrable only by surgeon or pathologist, eventually produced changes which were recognized on physical or laboratory examination. Diabetes and steatorrhea were caused by as few as two attacks of severe pancreatitis. In other instances these sequelae came on after milder attacks over a period of twenty-three years. Other sequelae developed as the result of pressure of the pancreas, which was enlarged by inflammation, abscess or cyst, on neighboring structures. These included the duodenum, the common bile duct and the superior mesenteric and splenic veins. Finally there were observed sequelae resulting from involvement of neighboring organs by disease.

---

[1] Comfort, M. W.; Gambill, E. E., and Baggenstoss, A. H.: Chronic Relapsing Pancreatitis: A Study of 29 Cases Without Associated Disease of the Biliary or Gastrointestinal Tract, Gastroenterology 6: 239 (April), 376 (May) 1946.

The attacks of pain persisted unchanged, grew worse, lessened or ceased. The progress of the disease did not necessarily follow a parallel course. Seven of the 29 patients have died from pancreatitis, its sequelae or other causes.

In the treatment medical or surgical measures or both were used. Medical treatment was palliative and supportive, with substitution therapy when needed. Surgical measures were used to relieve pressure on the duodenum or the common bile duct, to drain cysts or abscesses or to remove stones from the pancreatic ducts. Pain was sometimes relieved and remissions were induced by surgical measures which reduced pressure in the common bile duct, by drainage of cysts or by pancreatolithotomy. Partial or total pancreatectomy may be necessary in cases of disabling pain.

This paper appears to be a major contribution to the study of diseases of the pancreas and the upper part of the abdomen. Future work will, no doubt, solve the problem of etiology so that a rational basis for specific therapy may be found. Perhaps special attention might profitably be directed by surgeons and pathologists to the question of stenosis or occlusion of the main pancreatic ducts by intraductal papilloma, by inflammatory lesions or by concretions.

NITROGEN BALANCE

Protein intake and the maintenance of "nitrogen balance" have assumed much practical clinical importance. Success has followed the practice of maintaining nitrogen balance in a variety of clinical conditions through the use of parenterally administered protein hydrolysates or amino acid mixtures. A prolonged negative nitrogen balance may lead to a decrease in the plasma protein level, edema, anemia, lowered resistance to infection, increased susceptibility to certain toxic substances, the development of fatty liver or perhaps other serious sequelae.

Important is the essential amino acid content of the protein, the protein hydrolysate or the amino acid mixture itself. Studies on human subjects[1] have repeatedly shown that, if any one of the essential amino acids is lacking, the others are poorly utilized or may be excreted with a resulting "negative nitrogen balance." This phenomenon explains the "poor biologic value" of certain dietary proteins, such as gelatin, which is low in tryptophan, and gliadin of wheat. A recent comprehensive investigation[2] has demonstrated that there is a close mathematical correlation between the biologic value of a protein and the maximum relative percentage deficiency of any one of its component essential amino acids.

Other factors as yet poorly understood adversely affect nitrogen balance in man, as is seen in severe infections,[3] after trauma[4] or following burns.[5] In each of these conditions the negative nitrogen balance due to an excessive loss of nitrogen in the urine may be so severe that extremely large increases in protein intake, orally or parenterally, are required to reestablish nitrogen balance.

One interesting explanation[6] of the negative nitrogen balance suggests that increased amounts of one or perhaps more essential amino acids are required following burns or trauma for the repair of the damaged area or for detoxication. The body is thus "robbed," so to speak, of one or more essential amino acid, and the other amino acids cannot then be utilized and are excreted perhaps after being broken down to urea and other degradation products. In support of this concept the English workers have found that the administration of the essential amino acid methionine to severely burned subjects is followed by a significant increase in nitrogen retention. This interesting observation merits further careful investigation.

RUTIN THERAPY IN HEREDITARY HEMORRHAGIC TELANGIECTASIA

Hereditary hemorrhagic telangiectasia, or Rendu-Osler-Weber disease, is an uncommon but well established clinical entity characterized by multiple telangiectases, hemorrhages and hereditary transmission. Goldstein[1] in 1931 presented a comprehensive review of the literature on the subject, according to which there were some 90 to 95 families and about 500 to 550 persons affected with this condition. Epistaxis is the most frequent symptom, but bleeding from the skin or oral mucous membranes occurs in the majority of patients. The telangiectases usually do not appear before the age of puberty. In the third and fourth decades of life they become more numerous and more subject to hemorrhage. Anemia severe enough to be incapacitating often results from the long continued loss of blood, and a number of fatal hemorrhages have been reported. The frequency of internal bleeding in patients with hereditary hemorrhagic telangiectasia with hematemesis, hemoptysis, melena, hematuria and even cerebral hemorrhages has been emphasized by many authors. The true nature of hereditary hemorrhagic telangiectasia was established in 1901 by Osler, who separated it from the then large group of hemorrhagic diseases of uncertain origin. Weber differentiated the condition from hemophilia by the absence of sex-linked transmission and by the well recognized tendency for epistaxis to be the first manifestation. The two sexes are equally affected, and both males and females may transmit the disease to their offspring. In many families the disease appears to be inherited as a dominant characteristic, but several instances of skipped generations in afflicted families have been recorded.

[1] Goldstein, H. I.: Goldstein's Heredofamilial Angiomatosis with Recurring Familial Hemorrhages (Rendu-Osler-Weber's Disease), Arch. Int. Med. **48**: 836 (Nov.) 1931.

Boston in 1930 reported 3 cases of the disease with repeated gastric and rectal hemorrhages. The clotting time and the blood platelet count in his cases were normal. Recovery occurred with surprising rapidity even after extensive loss of blood. Renshaw [2] reported the first gastroscopic demonstration of telangiectases in the stomach of a typical case. Rundles [3] reported a case in which repeated nosebleeds had occurred from the age of 14 and in later life gastrointestinal hemorrhages severe enough to produce a severe, incapacitating anemia. Gastroscopy revealed multiple gastric telangiestases. Schuster [4] gave the first complete necropsy report of a case of hereditary hemorrhagic telangiectasia of the familial type. He pointed out that individual groups of dilated vessels are not permanent but rather vary from time to time in their number, size and tendency to bleed, even to the point of disappearing entirely. The frequency of widespread bleeding from many different sources with hemoptyses, melena, hematemeses, hematuria and even cerebral vascular accidents was emphasized in Schuster's necropsy report of the finding of telangiectases in the skin, nose, mouth, pharynx, larynx, trachea, stomach and duodenum.

According to a recent report by Kushlan [5] the literature at present (1946) contains records of some 175 families, with more than 1,000 members afflicted with this disease. He reports a typical case with a definite hereditary history, visible telangiectases and a tendency to bleed from the lesions. Nosebleeds and skin lesions began in childhood. The gastrointestinal hemorrhages began in the fourth decade. The chronic anemia resulting from the constant loss of blood was well controlled with oral iron therapy even after two episodes of severe gastrointestinal hemorrhage. The most recent gastric hemorrhage appeared to create a grave situation in spite of the treatment and five blood transfusions. At this point Kushlan gave his patient rutin, which he obtained from Griffith, in doses of 40 mg. three times a day. A remarkable change in the character of his patient's bleeding was noted within twenty-four hours after starting him on this medication. His daily epistaxis and bleeding from the gums ceased for the first time since childhood and they have not recurred at the time of this writing. Kushlan expresses the hope that rutin may prove to be a specific remedy in the treatment of hereditary hemorrhagic telangiectasia.

Scarborough [6] in 1939 presented evidence from experments on human subjects to prove the existence of a factor decreasing capillary fragility, this factor being vitamin P. He demonstrated vitamin P deficiency in man and distinguished between the spontaneous gross hemorrhage of scurvy and the spontaneous petechial hemorrhage of vitamin P deficiency. Rutin, which, like vitamin P, is a flavone glucoside, is supposed to have the same properties. According to Griffith [7] it is a constituent of a variety of plants, including tobacco, garden rue, forsythia, elder flowers and violets. Griffith administered rutin to 11 patients with increased capillary fragility for periods varying between twelve and sixteen months. Capillary fragility became normal in 8 of these within two months of beginning medication. Griffith concluded that at least in certain cases rutin appears to have the property of decreasing capillary fragility in subjects in whom this fragility is initially increased.

Current Comment

SURGICAL TREATMENT OF CONGENITAL CARDIOVASCULAR DEFECTS

Blalock's [1] recent report on 110 surgical interventions for the correction of congenital cardiac malformation extends the feasibility of helping the "blue baby." The operation suggested by Dr. Helen Taussig and developed by Blalock is designed to increase the flow of blood to the lungs and is accomplished by an end to side anastomosis of a systemic artery to one of the pulmonary arteries. This operation will not benefit all patients with persistent cyanosis. It is indicated only in malformations in which the primary difficulty is lack of adequate circulation to the lungs. The types of abnormalities likely to be benefited by the operation, according to Blalock, are the tetralogy of Fallot, pulmonary atresia with or without dextroposition of the aorta and with or without defective development of the right ventricle, truncus arteriosus with bronchial arteries and a single ventricle with a rudimentary outlet chamber in which the pulmonary artery is diminutive. In borderline cases with difficult diagnosis and a hopeless outlook an exploration is advisable, in the course of which the pressure in the pulmonary artery can be measured by using a needle and a water manometer. When the pressure is greater than 300 mm. of water, an anastomosis is not advisable. The anastomosis was successfully performed in 91 patients out of 110, with 16 fatalities or a mortality rate of 18 per cent. The subclavian artery was used in 46 patients, with 4 deaths. The innominate artery was used in 36 patients, with 11 deaths. The end of the carotid was anastomosed to the side of one of the pulmonary arteries in 9 patients. There was 1 death in this group. None of the patients had empyema or mediastinitis. There was no significant interference with the circulation of the arm on the side on which the subclavian artery was sacrificed or used for the anastomosis in any of the patients. Weakness or paralysis of the opposite side of the body in patients in whom the innominate or carotid artery was used either had cleared or was diminishing in all who survived the operation. Although some of the operations were performed too recently to allow an evaluation, Blalock believes that all but 1 of the patients who have survived the performance of an anastomosis are improved. It is believed that the artificial ductus in the remaining patients is patent, although a murmur cannot be heard in at least one of them. Heart failure or Streptococcus viridans endarteritis has not developed thus far in any of the patients. Blalock's studies, together with those of Taussig and of Potts and his associates,[2] recently reported in The Journal, reflect the tremendous improvement in prognosis for many infants with congenital heart disease.

PASTEURIZATION OF MILK

The value of pasteurization of milk in preventing the spread of milk borne disease is now well established. The Council on Foods and Nutrition of the American Medical Association in an official statement says, in part, "The pasteurization of milk is a public health measure. The public should demand pasteurized milk for drinking and the use of pasteurized milk in milk products. The dairy trade should universally adopt pasteurization in the interest of public health. Only pasteurized milk is granted recognition by the Council. There is no cogent evidence that pasteurized milk is significantly inferior nutritionally to raw milk." Progressive city health departments have long required compulsory pasteurization; in 1943 the Boston Health Department succeeded in adopting a regulation putting an end to the sale of raw milk in that city. Now the *New England Journal of Medicine* editorializes[1] with righteous wrath against a recent outpouring on the choice of milk by William Brady, M.D., syndicated health columnist. "Any old milk," according to Brady, "regardless of its source, quality or purity, is made safe for infant, child, invalid or adult by scalding . . ."! Certified milk is Brady's first choice and pasteurized milk, though he appears to have heard of it, is not even his third. This irresponsible pronouncement can only reflect ignorance of or disbelief in modern scientific concepts. William Brady's individual whims and foolish notions about removal of tonsils, injection methods, prevention of infection, the uses of iodine, and a half dozen other subjects, have been circulated by newspapers to the detriment of the public health. Every time he cuts loose, as he seems to do more and more frequently with advancing age, The Journal receives communications from doctors who want to know why something is not done to prevent the perpetration of his fallacies. Their communications might better be addressed to local editors who purchase the column from the syndicates and must therefore be responsible for its appearance in the newspapers they edit.

CAUDAL ANESTHESIA IN OBSTETRICS

Edwards and Hingson[1] reported in 1942 a new *method for relief of pain in childbirth by extradural* introduction of fractional doses of anesthetic substances through the sacral hiatus into the sacral canal. Caudal anesthesia combines, according to the authors, the advantages of Lemmon's spinal anesthesia with the safety, simplicity and effectiveness of the extradural nerve block by using the sacral hiatus approach to the sacral canal and the peridural space. The anesthesia can be continued indefinitely by serial injections of the anesthetic solution at intervals in amounts varying with individual cases. A recent report[2] presents a statistical evaluation of the results of delivery with continuous caudal anesthesia done under the supervision of Drs. Hingson, Vaux and Lull at the Philadelphia Lying-in Unit of the Pennsylvania Hospital. This group of 2,516 mothers delivered of 2,546 infants was compared with the deliveries of 1,000 women during the years 1942 to 1943 at the same hospital under the older methods of delivery. Data regarding the mothers in the two groups indicate that when they came to delivery they were comparable with respect to age, parity, state of health and many other factors that might influence the outcome of childbirth. Metycaine was the drug used for continuous caudal analgesia in 99 per cent of the cases. Of the 2,516 mothers 90.4 per cent received complete relief from pain, 4.3 per cent received partial relief, and in only 5.3 per cent was there failure to obtain relief from pain. There was no evidence of danger to the mothers delivered with continuous caudal analgesia, although one third of them showed a drop in systolic blood pressure during the administration of the drug. The postpartum action of the uterus was better in the caudal than in the control group. There were fewer stillbirths and fewer deaths of infants during the first week of life in the caudal than in the control group. More favorable results for the caudal group were indicated in terms of comfort of the mother during labor and the survival of the infant during the dangerous first week of life.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Jan. 23, 1947.

Opposes Transfer of St. Elizabeths to District of Columbia

In vigorous fashion Dr. Winfred Overholser, nationally known superintendent of St. Elizabeths mental hospital, has expressed his opposition to the proposal that it be transferred from the federal government to the District of Columbia for use as a master hospital and welfare center. He said: "I have no enthusiasm, personally, over seeing the hospital transferred to the District as an omnium gatherum, hodge podge bedlam for various city institutions. It would cost the hospital its reputation as a nationally recognized teaching and research institution. It would be a return to the Middle Ages. A calamity." He pointed to slashes in health department budgets and cited the psychiatric ward at Gallinger Municipal Hospital to illustrate what would happen to St. Elizabeths under municipal direction. "An elevator shaft was built years ago when the building was erected, and the city has never yet provided funds for the elevator." Dr. Overholser also criticized the present method of commitment to the hospital through a commission consisting of two psychiatrists and a lawyer. He pointed out that the District of Columbia Medical Society is preparing a bill to provide voluntary admission to St. Elizabeths Hospital for residents of the area.

Proposed New Hospital Center in Nation's Capital

A special committee is studying possible sites for the proposed 20 million dollar District of Columbia hospital center, for which $2,750,000 has been asked in the 1948 budget to buy land and make plans for the center. The committee, composed of representatives of Garfield, Emergency and Episcopal hospitals, government officials and one public representative, must decide which facilities of the three hospitals can be combined in jointly operated units and which can be kept separate. On the committee are Surgeon General Thomas Parran, U. S. Public Health Service; Admiral Ross T. McIntire, former surgeon general of the Navy; Chief Justice Bolitha T. Laws of the District of Columbia; Henry P. Blair, of Episcopal Eye, Ear and Throat Hospital; George A. Garrett, Central Dispensary and Emergency Hospital; William R. Castle, Garfield Memorial Hospital; District Health Officer George C. Ruhland, and others.

Stable Relations Between Government and Research Science Reported by Dr. Bush

Dr. Vannevar Bush, president of the Carnegie Institution of Washington, told guests at a meeting of ten District of Columbia engineering societies that stable relations between government and research science are being developed. He reported that the present year promises to be of great significance in scientific development, and he advocated more clear cut lines of command in agencies sponsoring basic research under the billion dollar a year outlay of the government for research and development. Dr. Bush described the Office of Scientific Research and Development, of which he is director, and the Joint Research and Development Board, which he serves as chairman.

Testimony Favoring Universal Training

The President's advisory commission has reported favorable testimony on universal training to Mr. Truman from Army and Navy leaders, military organizations and the American Legion. The commission was appointed to study the problem and devise a plan of military training. Reports of the final session are awaited. Among those already heard was Major Gen. Norman T. Kirk, Army Surgeon General, who related plans for safeguarding the health of trainees.

Official Notes

A. M. A.-N. B. C. CENTENNIAL BROADCASTS

In celebration of the Centennial year of the American Medical Association, 1947, the twelfth annual series of the A. M. A.-N. B. C. dramatized broadcasts is devoted to features of medical progress in the United States during the hundred years of the existence of the American Medical Association.

For purposes of the broadcast, the United States is divided into twenty-five regions. These regions have been chosen with a view to grouping together states which have similar history and similar general characteristics, such as the four states of the Rocky Mountain region, the two groups of New England states, the Southeastern and the Central Southern groups.

One broadcast is devoted to medical progress in each of these regions, and the twenty-sixth and closing week will deal with the hundred years of the American Medical Association from a nationwide point of view.

The title for the series is "Doctors—Then and Now" and the theme is "A Century of Progress by American Medicine."

The dramatic scripts are written by William J. Murphy, veteran medical script writer responsible for most of the previous A. M. A.-N. B. C. series; production is directed by Norman Felton, director of the two preceding series; Joseph Gallicchio is again directing the N. B. C. orchestra. Arrangements with N. B. C. have been made through the office of Miss Judith Waller, Public Service Director, Central Division, National Broadcasting Company.

The dates for January with topics were announced in a previous issue of THE JOURNAL. The four dates for February with topics are as follows:

February 1.—*Illinois, Iowa;* subject John Evans; the speaker, to be announced, will speak from station WHO at Des Moines.
February 8.—*Maine, Vermont, and New Hampshire;* subject Nathan Smith; speaker to be announced will speak from station WRDO at Augusta.
February 15.—*Idaho, Oregon and Washington;* subject Marcus Whitman; the speaker, to be announced, will speak from station KGW at Portland.
February 22.—*Nebraska;* subject J. A. Waggoner; Dr. Roy W. Fouts will speak from station WOW at Omaha.

. Subsequent programs will be announced as soon as they are ready.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 10-11. Dr. Victor Johnson, 535 N. Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Feb. 7-8. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

American Academy of Orthopedic Surgeons, Chicago, Jan. 25-30. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.

Central Surgical Association, Chicago, Feb. 20-22. Dr. Walter G. Maddock, 250 East Superior St., Chicago, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 17-20. Dr. Glenn D. Earlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24-27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Council on Medical Service

MEDICAL FACILITIES AVAILABLE IN RURAL AREAS OF THE STATE OF VIRGINIA

A report of the Virginia Advisory Legislative Council to the governor and the general assembly of Nov. 12, 1945 pursuant to senate joint resolution number 16 on the medical facilities available in rural areas of the state has been reprinted and distributed.

The nine member advisory legislative council consisted of Charles R. Fenwick, lawyer, chairman; I. C. Riggin, M.D., state health commissioner, vice chairman; M. M. Long, senator, patron of the resolution; W. E. Garnett, Ph.D., rural sociologist; H. B. Mulholland, M.D., president, state medical society; Phillip S. Smith, M.D., vice president, state medical society; J. M. Emmett, M.D., W. J. Sturgis, M.D., and W. T. Sanger, Medical College of Virginia.

The report includes eight basic recommendations for immediate action and reviews data and information in support of the recommendations made as well as suggested state legislation on "Licensing and Inspection of Certain Kinds of Hospitals."

A brief of the summary basic recommendations for immediate action are:

1. Expansion of public health facilities to include complete coverage of the state by local public health departments.
2. Expanded, correlated hospital and health center systems.
3. Development of the methods of furthering the financing of essential medical care for every one by (*a*) public funds in the amount of 30 cents per capita for the needy; (*b*) prepayment plans for hospital, surgical and medical care.
4. To help to increase the supply of rural doctors through creating loan funds for medical students to be accompanied by a pledge of stipulated service in rural areas.
5. Licensing of hospitals and nursing homes by the state department of health.
6. Providing consultants on hospital location and planning within the state.
7. Creating revolving hospital and health center construction and equipment loan fund with interest at 2 per cent to assist local hospital and health center boards.
8. That the whole problem of medical facilities and that of promotion of needed measures in the field be studied further by a commission.

In discussing the cost of medical care in 1941, reports of approximately 2,400 Virginia rural families gave an average expenditure of $60 a year per family for all types of medical care. About one sixth of these families had medical care bills of more than $100 a year, and nine tenths of the families had some expense for medical care during the year. The report continues:

"Aside from the humanitarian considerations, adequate medical care within the financial reach of rural people is a matter of concern to urban centers as well as to country folk themselves.

"The country is a seed bed from which cities must be constantly replenished. The good health of the workers from rural areas should be a matter of great interest to industrial concerns."

In discussing further patterns of medical practice, the report points out that trends today definitely indicate that a much smaller percentage of medical care will be delivered to the homes of the sick. When people are desperately ill they increasingly seek medical care in a doctor's office, a medical center or a community hospital.

Another trend which is likely to assume even more rapid tempo is the practice of doctors, dentists and technical personnel to associate themselves in groups with advantage both to the patient and to the practitioner.

In discussing medical services, the Council reported that some better method of financing medical services is essential to the improvement of the medical care situation. It believes that plans to this end should be based on the following governing principles: (1) Every one, as far as able, should pay the cost of his medical care; (2) when a family is financially unable to pay for essential medical services, the cost should be borne wholly or in part by the public, thus making real the principle that every one should receive medical and surgical care as an inherent right; (4) the administration of public aid for medical care should, as far as possible, be local; (5) any program for financing medical services should be such as to encourage the medical care essential to positive health; (6) greatly extended use should be made of the insurance principle in connection with payment for medical care; (7) any plan adopted should be sufficiently flexible to be adjustable to an expanding medical care program.

Medical Legislation

STATE LEGISLATION

Colorado

Bill Introduced.—S. 31 proposes to authorize the state board of medical examiners to grant licenses to practice "naturopathy," defined as "the art and science of applied healing forces; thus enabling the physician to prescribe or administer to human trauma or disease by applying any one or more of the physiological, mechanical, electrical, manual, chemical, biological, psychological, or material forces or agencies in restoring a normal state of being, as taught in Naturopathic Colleges." Naturopaths would be prohibited from using the prefix Doctor or Dr. without following his or her name with Naturopathic Physician, Naturopath, or N. D.

Massachusetts

Bills Introduced.—H. 145 proposes to add a new section to the general laws which would authorize a trial court to direct that the complainant, her child and the defendant, in an illegitimacy proceeding, should submit to one or more blood tests to determine whether or not the defendant can be excluded as being the father of the child. The results of such test would be admissible in evidence in cases in which definite exclusion is established. The bill further proposes that refusal to submit to such test may be disclosed on the trial unless good cause is shown to the contrary. S. 26 proposes that any duly registered physician shall be entitled, on application, to the privileges of practicing in, and having his patients admitted to, any public or semipublic hospital or any hospital supported in whole or in part by contributions from the commonwealth or from a city or town or any hospital which solicits contributions for its support from the public. S. 29 proposes the establishment of a hospital planning board of five members, at least two of whom shall be duly registered physicians. This board would be the sole state agency to carry out the purposes of the federal hospital survey and construction act. S. 47 proposes that whoever experiments or operates in any manner whatsoever upon any living dog or cat for any purpose other than the healing or curing of said dog or cat shall be punished by a fine of not less than $100 nor more than $500, or by imprisonment for not less than three months nor more than one year, or by both such fine and imprisonment. S. 51 proposes the creation of a board of registration of chiropractors and defines chiropractic as "the science of locating, and removing, by hand only, interference with the transmission or expression of nerve force in the human body, and the correction of misalinement or subluxations of the vertebral column. It excludes operative surgery, prescription or use of drugs or medicine, or the practice of obstetrics, except that the x-ray may be used solely for the purpose of examinations; chiropractor is defined who lawfully practices chiropractic." The proposal would prohibit a chiropractor from using in connection with his name any term other than "Registered Practitioner of Chiropractic" and would require annual registration of each licentiate.

North Dakota

Bill Introduced.—H. 23 proposes regulations for the licensing of maternity homes for unmarried mothers and, in connection therewith, proposes that every birth occurring in such a home shall be attended by a legally qualified physician, if available, otherwise by a registered nurse until the services of a legally qualified physician may be obtained.

Tennessee

Bill Introduced.—H. 20 proposes to repeal the 1943 law creating a board of naturopathic examiners. The purpose of this proposal is to prevent the practice of naturopathy in Tennessee.

GOVERNMENT SERVICES

ARMY

ARMY APPEALS FOR MORE NURSES

Appointment of three hundred nurses who have not had prior military service in the Army of the United States in the grade of Second Lieutenant has been authorized by the War Department. Because of the acute shortage of nurses authorization for additional nurses will be made as soon as 80 per cent of the quota is filled. The appointment will be for the duration and six months thereafter, or for a period of eighteen or twenty-four months. There is no provision for appointments in the Regular Army Nurse Corps until legislation is enacted to establish the corps for peace time operations; however, nurses accepting temporary appointment in the Army of the United States will be considered for transfer to the Regular Army provided they qualify.

Graduate registered nurses under 34 years of age, single or widowed without dependents under 14 years of age and in good physical condition who are interested in army nursing should apply for application blanks to the Surgeon General's Office, Pentagon Building, Washington 25, D. C.

NEW DIRECTOR OF ARMY INSTITUTE OF PATHOLOGY

The Surgeon General has announced the appointment of Col. Raymond O. Dart, M. C., as director of the Army Institute of Pathology, Washington, D. C., to succeed Col. James E. Ash recently retired. Colonel Dart served about eight years before the war at the Army Medical Museum and Army Institute of Pathology and in all has practiced pathology for more than twenty-five years.

Colonel Ash, who was director of the Institute of Pathology for the past nine years, is now the scientific director of the American Registry of Pathology, which is a major department of the institute and which is sponsored by the Division of Medical Sciences of the National Research Council.

GENERAL MacARTHUR REPORTS ON HEALTH CONDITIONS IN JAPAN

In his October report General MacArthur stated that the nationwide program for the immunization of 17,000,000 children in Japan against diphtheria was continued, that Asiatic cholera was considered eradicated in Japan and also no longer a quarantine problem, that the incidence of typhoid had declined and that a venereal disease control program aimed at educating the entire Japanese population had been initiated. Two more factories had been approved for the manufacture of penicillin during October, and 80 per cent of Japanese bombed out dentists had been restored to practice. Progress in the direction of medical reform continued with the formation of a Medical Practitioners State Examination Inquiry Committee, the appointment of twenty-two physicians as medical school inspectors, and the appointment of new members to the council for the reorganization of the Japan Medical Association.

ARMY MEDICAL EXHIBIT OPEN TO PUBLIC

The Army Medical Department Exhibit which had its premier showing at the annual session of the American Medical Association last June in San Francisco, was opened to the public January 6 in the Museum of National History of the Smithsonian Institution, 10th and Constitution Avenue N.W., Washington, D. C. This, the first public showing of the exhibit, will close January 27. It has been shown to medical audiences in Philadelphia, Cleveland, Detroit and Miami. The entire field of medicine is represented in this exhibit. Fully assembled, it covers half the area of a football field and requires three railroad freight cars when in transit.

ARMY AWARDS AND COMMENDATIONS

Major General Norman T. Kirk

Major General Norman T. Kirk, Surgeon General of the Army, was awarded the Legion of Merit on Dec. 6, 1946 in a ceremony in the Pentagon. Major Gen. Henry S. Aurand, formerly commanding general of the Sixth Service Command, made the presentation. The citation read as follows: "Major Gen. Norman T. Kirk rendered exceptionally meritorious service as commanding officer, Percy Jones General Hospital, from June 15, 1942 to April 13, 1943. His conspicuous performance as an organizer, administrator and professional surgeon culminated in the establishment of the country's largest Army Hospital Center, which has been unexcelled for eminent achievement in military medicine."

Lieutenant Colonel Joseph L. Goldman

The Army Commendation Ribbon was recently awarded to Lieut. Col. Joseph L. Goldman, M. C., A. U. S., of New York. "As chief of the ear, nose and throat service at William Beaumont General Hospital," said the citation, "Lieutenant Colonel Goldman planned and organized his ward and clinic so as to render meritorious service to an exceedingly heavy patient load, with limited personnel, maintaining patient welfare at the highest level. By his masterful integration of clinical material, operative schedules and didactic periods, Lieutenant Colonel Goldman gave instructions advancing the professional knowledge of the Regular Army Medical Corps officers. . . . His services reflect great credit on the Medical Corps of the United States Army." Dr. Goldman graduated from the Long Island College of Medicine, Brooklyn, and entered the service Aug. 11, 1942.

Lieutenant Colonel Wilfred Bloomberg

The Legion of Merit was recently awarded to Lieut. Col. Wilfred Bloomberg, M. C., A. U. S., of Cambridge, Mass., for meritorious service as psychologic examiner and consultant in neuropsychiatry, Office of Surgeon, First Service Command, from July 1942 to August 1945. By his professional knowledge and loyal devotion to duty, states the citation, he was responsible for the establishment of psychiatric methods and standards of induction which became the model for the entire country. His wise counsel was instrumental in restoring to duty or returning to useful civilian life the majority of psychiatric casualties treated in these hospitals and materially aided the nation's war effort. Dr. Bloomberg graduated from Harvard Medical School, Boston, in 1928 and entered the service July 10, 1942.

Lieutenant Colonel Arthur P. Long

The Legion of Merit was recently awarded to Lieut. Col. Arthur P. Long, M. C., A. U. S., of Needham, Mass., who was the director of the Epidemiology Division, Office of the Surgeon General, from April 1941 to August 1945. He actively participated in the formulation of the Army's program of military preventive medicine, and his meritorious achievements, which significantly contributed to the maintenance of low infectious disease rates in our armed forces, were especially mentioned in the citation. Dr. Long graduated from the State University of Iowa College of Medicine, Iowa City, in 1934 and entered the service May 23, 1942.

Lieutenant Colonel Francis R. Dieuaide

The Legion of Merit was recently awarded to Lieut. Col. Francis R. Dieuaide, M. C., A. U. S., of Boston, who served as chief, Tropical Disease Treatment Branch, Office of the Surgeon General, during the period February 1943 to September 1945. The citation attributed the splendid record of the Medical Department in the effective treatment of tropical diseases in large part to his professional skill, able direction and loyal devotion to duty. Dr. Dieuaide graduated from Johns Hopkins University School of Medicine, Baltimore, in 1920 and entered the service Nov. 1, 1940.

VETERANS ADMINISTRATION

PROPOSED CANCER HOSPITAL IN CHICAGO

At a conference of cancer specialists, Veterans Administration officials, U. S. Army engineers and architects in Chicago January 5 first plans were drafted for the proposed Veterans Administration cancer hospital on the campus of Northwestern University. The hospital, which is the only veterans' hospital being planned for cancer treatment and research, will have a capacity of 600 beds and probably an additional capacity for 200 outpatients.

Among those who attended the conference were Col. H. E. Brown, representing the Veterans Administration; Col. W. E. Jeffrey, representing the chief of army engineers; Col. W. P. Trower, district engineer; Dr. Curtis F. Burnam, chief of staff of the Kelly clinic, Baltimore; Drs. J. Roscoe Miller, Loyal Davis, John S. Gray and William B. Wartman, all of Northwestern University Medical School; Dr. A. C. Ivy, vice president of the University of Illinois; Dr. Henry N. Pratt of Memorial Hospital, New York; Dr. P. R. Copeland of the Veterans Administration and Dr. N. C. Trauba, clinical director of the Veterans Hospital, Hines, Ill.

POSTGRADUATE PROGRAM SUCCESSFUL

The program for post graduate studies inaugurated a year ago on an experimental basis at Yale University School of Medicine, New Haven, Conn., has proved highly successful in filling in the gaps in the research work and hospital training of the younger men of the medical profession service with the armed forces. The seventy students in the course are enrolled under the G. I. Bill of Rights and one-half of them are staying on for a second year of advanced study, according to Francis G. Blake, Dean of Medical Schools. They are all working in specialized fields of medicine. There are no formal entry periods because of the different times when the medical officers are discharged from the service. They are merely enrolled in the course provided that there are vacancies at the time of their discharge, and their work begins immediately. The course will continue as long as demand for it exists.

BIDS FOR NORTH DAKOTA HOSPITAL REJECTED

Army engineers have rejected all bids on the proposed Veterans Administration hospital at Minot, N. D., the War Department has announced. The low bid on this 150 bed hospital was $3,927,000 as compared with the government estimate of $3,128,190. Steps will not be taken to readvertise for bids on this hospital until a decision is reached on the bid for the hospital at Grand Junction, Colo., which is almost identical with the Minot design. The low bid however on the proposed Grand Junction hospital was $3,463,800 as compared with the government estimate of $2,910,000. Army engineers are negotiating also with the low bidders on the Peekskill, N. Y., proposed hospital, which was $23,739,409 as compared with the government estimate of $19,185,119. These three hospitals were all designed by the construction service of the Veterans Administration.

EXPERIMENTS AND TRAINING IN MAKING PROSTHESES

Clinics at which eligible veterans may be fitted with new plastic eyes or have repairs and alterations made to those they are wearing are in operation in eight cities over the country. Later the clinics will be expanded to include fitting and repairs for plastic noses, ears and hands. Clinics are in operation in Boston, New York, Atlanta, Cleveland, Chicago, Los Angeles, San Francisco and Baltimore. Similar clinics will be opened in Memphis, Tenn.; Dallas, Texas; Minneapolis; Denver; Portland, Ore., and at the army's Valley Forge Hospital, Phoenixville, Pa., when this installation is transferred to the Veterans Administration.

In order to supply the latest prostheses of this type, experiments are being carried out at the University of Maryland. A training school to acquaint Veteran's Administration doctors and technicians with progress in the experiments and to train them in the art of building the prostheses will be conducted at the University of Maryland School of Medicine opening early in January. Specialists from over the country will attend.

PUBLIC HEALTH SERVICE

EXAMINATION FOR THE REGULAR CORPS

A competitive examination for appointment in the Regular Corps of the U. S. Public Health Service in the grades of Assistant Surgeon (First Lieutenant) and Senior Assistant Surgeon (Captain) will be held at various times and in various cities between February 4 and March 17.

Regular Corps appointments are permanent in nature and provide opportunities to qualified physicians for a life career in one or more of a large number of fields including research, general hospitals, special hospitals, foreign duty and federal, state and local public health programs. Assignments are made with all possible consideration of the officer's demonstrated abilities and experience. There is an ample opportunity for professional growth and development.

All applicants must be at least 21 years of age and citizens of the United States, must present a diploma of graduation from a recognized medical school and satisfactorily pass a physical examination performed by Public Health Service officers when directed on successful completion of the oral and written examination.

Applicants for the grade of Assistant Surgeon must have had at least seven years of educational and professional training or experience, exclusive of high school. Applicants for the grade of Senior Assistant Surgeon must have had at least eleven years of educational and professional training or experience, exclusive of high school.

Application forms may be obtained by writing to the Surgeon General, U. S. Public Health Service, Washington 25, D. C. These should be retained and presented to the board at the time the applicant appears for the oral examination.

Entrance pay for an Assistant Surgeon with dependents is $3,811 a year and for Senior Assistant Surgeon with dependents, $4,351 a year. Promotions are at regular intervals up to and including the grade of Medical Director, which corresponds to full Colonel, at $8,551 a year. Retirement pay at age 64 is $4,950 a year. Full medical care including disability retirement at three-fourth's pay is provided.

EXAMINATIONS FOR THE APPOINTMENT OF NURSES

Examinations will be held in twenty-one cities throughout the country during February and March for the appointment of nurses to the first three grades of the Regular Commissioned Corps of the U. S. Public Health Service. The positions open are in the grades of Junior Assistant Nurse Officers, comparable to the rank of 2d lieutenant in the Army; Assistant Nurse Officer (1st lieutenant) and Senior Assistant Nurse Officer (captain). Any registered nurse who is a citizen of the United States and has a diploma from a state accredited school of nursing connected with a hospital maintaining a daily census of not less than 50 patients may take the examination provided she is at least 18 years old and a graduate of an accredited high school. Preference will be given to graduates with degrees. Graduates for Assistant Nurse Officer must have these qualifications and also must have been out of school at least seven years, the intervening time having been devoted to educational and professional experience, and they must also have an academic degree or have served at least four years in the Public Health Service, or the Army or Navy Nurse Corps.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

CALIFORNIA

Edward Rogers Appointed Dean of School of Public Health.—Dr. Edward S. Rogers will take over his duties as dean of the University of California School of Public Health in February. Dr. Roberts has been assistant commissioner in the New York State Department of Health. He is a native of Boston and a graduate of Harvard Medical School and Johns Hopkins School of Hygiene and Public Health. Dr. William McD. Hammon, who has served as acting dean, will continue as faculty member.

First Francis I. Proctor Lecture.—The first Francis I. Proctor Lecture in Ophthalmology was given at the University of California Medical School, Berkeley-San Francisco, by Dr. Kenneth Swan, University of Oregon Medical School, Dec. 20, 1946 on "Some Contemporary Concepts of Pharmacology and Toxicology of the Cornea." The yearly lecture was recently established at the school by a $20,000 gift from Mrs. Francis I. Proctor in memory of her husband, who it is said induced Noguchi to make his studies in trachoma and through whose generosity and determination the confirmation of the etiology of trachoma was made possible. It was Dr. Proctor's interest in furthering ophthalmology in the Western part of the United States that resulted in the establishment of this lecture on the Pacific Coast.

CONNECTICUT

Personal.—Dr. John D. Booth, Danbury, has been appointed a member of the Connecticut Medical Examining Board to fill the vacancy caused by the death of Dr. Daniel C. Patterson.——Dr. William Bowers Smith, formerly chief medical officer for the Connecticut Selective Service System, has been appointed surgeon general with the rank of colonel on the military staff of Governor-Elect James L. McConaughy. A reserve medical officer since 1924, Dr. Smith has for many years been flight surgeon of the Connecticut Department of Aviation.——A farewell testimonial dinner was given to Dr. Michael A. Kinsella and his wife, Dr. Gertrude C. J. Kinsella, practicing physicians in New Britain for many years, on their announced retirement from active practice. They will make their home in Florida.——Dr. Elias Pratt, after fifty-six years of medical practice in Torrington, has presented his resignation as city health officer and school and city physician, posts which he has filled for many years. Dr. Pratt also has served as president to both the Connecticut State Medical Society and the Litchfield County Medical Association. He will make his home with his son in Essex.

ILLINOIS

Galesburg Army Hospital Leased to State University.—The War Assets Administration on January 10 approved the leasing of the former U. S. Army Mayo General Hospital, Galesburg, to the University of Illinois for use as a branch. The university had taken over the hospital last fall under an interim permit and has been holding classes there for several hundred students. The leased property includes 155 acres and 128 buildings constructed by the government during the war at a cost of $4,546,659. The 116 connected one story buildings used for classrooms can accommodate 2,000 students; the other buildings are used for infirmary, recreation, mess hall and laundry buildings.

Training Program for Public Health Physicians.—The Illinois Department of Health, Springfield, has developed a training program in order that the needs of the state for trained and experienced public health physicians may be more adequately met. Individuals interested in entering this program should apply to the director of the Department of Health. Appointees are selected by a committee on the basis of qualifications after a personal interview. Appointments are made through the Civil Service Commission. Persons who successfully complete the training agree to remain in public health work in Illinois for at least two years. Applicants must be citizens of the United States preferably not more than 35 years of age, graduates of an approved medical school, with at least one year of rotating internship and licensed to practice or eligible. The training period is divided into an orientation phase and an academic phase, the former consisting of at least six months of practical field service and the latter of one year of training in a postgraduate school of public health. After successfully completing both phases of the training program the individual is eligible to take the Illinois Civil Service examination for Public Health Physician I or II and is qualified for appointment as health officer or assistant health officer in a county or city health department. During the orientation period trainees not yet licensed to practice medicine receive $250 per month and licensed physician trainees receive $310. During the academic training period each trainee receives $310 per month plus tuition and cost of transportation to and from school.

Chicago

Tuberculosis Societies to Hear Dr. Barach.—At a meeting of the Chicago Tuberculosis Society and the Tuberculosis Institute of Chicago and Cook County, Friday, January 31, Dr. Alvin L. Barach, Columbia University College of Physicians and Surgeons, will discuss "Physiological Therapy in Respiratory Diseases" with special reference to recent developments in the treatment of pulmonary tuberculosis and pulmonary emphysema. John S. Gray, Ph.D., professor of physiology, Northwestern University Medical School, Chicago, and Dr. Andrew C. Ivy, vice president, University of Illinois College of Medicine, Chicago, are scheduled to present discussions following the lecture.

Cancer Symposium.—Forty physicians representing Illinois medical societies attended a symposium on cancer conducted by the Illinois Division of the American Cancer Society here January 20-24. Lectures, conferences and clinics at the University of Illinois, Northwestern University, University of Chicago, Loyola University, Michael Reese Hospital and Mercy Hospital made up the program. The symposium, part of the cancer societies' program of professional education, was arranged by Drs. Warren H. Cole, University of Illinois College of Medicine; Alexander Brunschwig, University of Chicago School of Medicine; Loyal Davis, Northwestern University Medical School; Herbert E. Schmitz, Loyola University School of Medicine, and John A. Rogers, the society's executive medical director in Illinois.

Lack of Sanitation in Restaurants and Taverns.—It appears in a report for the Chicago and Cook County health audit that investigators from the U. S. Public Health Service recently made a sampling survey of Chicago restaurants, cafeterias and taverns. The eating and drinking places in Chicago were given a rating of only 31.5 out of a possible 100 points under the Public Health Service standards. These findings were based on representative samplings of permanent or fixed establishments, of which Chicago has about 17,000. Chicago hospitals, on the basis of a few sampled, rated even lower than restaurants. Among the sections of the report are the following:

> Ninety-nine per cent of the establishments surveyed violated the item pertaining to disinfection of dishes and utensils; that item pertaining to back-siphonage into water supplies, and the item covering garbage disposal methods.
>
> Ninety-eight per cent violated the item pertaining to the cleaning of dishes and utensils; 98 per cent were deficient in items pertaining to toilet facilities, and 93 per cent violated the item pertaining to the cleaning of equipment.
>
> Antiquated dish washing equipment was found in establishments scattered throughout the city, indicating that little attention had been directed to applying modern methods and technics to an age old job. Water temperatures were frequently below the required 170 degrees, and chlorine concentrations sufficient to kill germs left on utensils, cups and glasses . . . were often absent. The wiping of dishes and glasses, an unnecessary operation when the disinfection water is hot enough, generally were done with dirty towels.
>
> The practice of permitting perishable foods, such as cooked meats, cream pies and salads, all excellent mediums for bacterial multiplication, to remain at room temperatures and exposed to contamination . . . was most noticeable. "It is quite obvious," the report said, "that the restauranteurs recognize the value of window dressing for the public benefit." Elaborate and ornate appointments were obvious in many establishments, while in the kitchens vermin and filth were found.

The remedies for these insanitary conditions were said to include revamping of the city code and increasing the food inspection staff of the Chicago Health Department and improvement in the methods of hospitals.

MARYLAND

Appoint Radiologist for Johns Hopkins Hospital.—Dr. Russell H. Morgan, former associate professor of radiology at the University of Chicago, has been named professor in the newly created department of radiology at Johns Hopkins University, Baltimore, and will also serve as radiologist in chief at Johns Hopkins Hospital. Formerly a section of the division of surgery, radiology has been made an independent department of the two institutions in order to provide better clinical service to the hospital, improve instruction in the university and promote research in the field.

MASSACHUSETTS

Hospital Sponsors Evening Lectures.—Dr. Samuel A. Levine, Harvard Medical School, Boston, gave the opening lecture in a series presented under the sponsorship of the Council of the House Officers' Association of Boston City Hospital January 7. His subject was "Cardiac Arrhythmias and the Use of Quinidine."

Massachusetts Medico-Legal Society.—The midwinter meeting of the Massachusetts Medico-Legal Society will be held February 12 in Magrath Library of Harvard Medical School, Boston at 2:30 p. m. Under problems of procedure Dr. Timothy Leary, Boston, will discuss "Circumstances in which the filing of an incomplete 'under investigation' death certificate may be desirable." Dr. Leroy T. Stokes, Haverhill, will speak concerning "Reimbursement of undertakers for transportation of bodies and use of mortuary facilities." "When and how a medical examiner should report a death for inquest" is the subject of a discussion by Dr. David C. Dow, Cambridge. There will also be four short reports of cases.

MICHIGAN

Physicians Cited for Volunteer Service.—At the annual meeting of the Ingham County Medical Society, Lansing, in December 1946, 54 members of the society were awarded medals with citations for at least two years of volunteer service as examining physicians or medical advisers to the selective service system during the last six years. The presentations were made by Brig. Gen. LeRoy Pearson, director, state selective service system. Dr. Franklin L. Toost, Holt, president of the county society, presided and Dr. Robert S. Breakey, Lansing, president-elect, later assumed the presidency of the society.

Annual Hospital Clinic Day.—Mount Carmel Mercy Hospital, Detroit, will hold its annual clinic day January 29. Among the morning speakers will be Dr. Willard Owen Thompson, professor of medicine, University of Illinois College of Medicine, Chicago, whose subject will be "Glandular Disturbances of Childhood." Dr. Richard W. TeLinde, professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, will address the clinic on "Tumors of the Female Genital Tract," and Dr. Leland S. McKittrick, professor of surgery, Harvard Medical School, Boston, will speak on "Peptic Ulcer, Surgical Management." A luncheon will be served at 12:30 p. m. and an evening banquet is scheduled at the Book-Cadillac Hotel.

NEBRASKA

Changes in Health Officers.—Dr. Howard C. Stewart, Franklin, Tenn., has been appointed health officer of Lincoln to succeed Dr. Leroy L. Fatherree, who resigned to take a similar position in Omaha.

Dr. Miner Heads Counselor District.—Dr. H. R. Miner, Falls City, was elected president of the southeast Nebraska counselor district of the Nebraska Medical Society at its December meeting in Beatrice, the first to be held in four years. The district is made up of Nemaha, Johnson, Pawnee, Gage and Richardson counties. Its next meeting will be held in Falls City in May.

NEW YORK

Expanded Tuberculosis Program.—Of approximately 10,000 state employees in Albany, 8,519 have received free chest x-ray examinations and of 8,218 roentgenograms thus far interpreted 25 indicate active tuberculosis. Dr. Robert E. Plunkett, Troy, head of the state tuberculosis control program, said that with few exceptions these cases of tuberculosis were newly discovered. This illustrates, he said, the value of this type of case finding.

Cancer Teaching Day.—A number of authorities on cancer addressed physicians in Rensselaer County at a cancer teaching day, December 12, at Troy under the auspices of the Medical Society of the County of Rensselaer, Tumor Clinic Association of the State of New York, Medical Society of the State of New York and the division on cancer control of the New York State Department of Health. Drs. Ranald E. Mussey, Troy, president of the county medical society, and Clement J. Handron, Troy, chairman of the society's legislative committee, presided.

Rehabilitation Hospital for Spastic Children.—A rehabilitation hospital for spastic children which would serve as a pilot plant for investigation and treatment of cerebral palsy for the state and nation will be established by the University of Rochester School of Medicine and Dentistry in cooperation with the New York State Health Department and the National Foundation for Infantile Paralysis. Governor Thomas E. Dewey has included in his 1947 budget message to the New York state legislature an appropriation of $150,000 for annual operating cost of the proposed clinic. In addition, a five year program under a $292,000 grant in aid was made to the university last July by the National Foundation for Infantile Paralysis for basic research in both cerebral palsy and infantile paralysis. Mr. and Mrs. Ernest L. Woodward, LeRoy, have offered the university a $500,000 estate of more than 50 acres in LeRoy, including a spacious residence that will accommodate about 40 patients from 2 years of age and up and a staff of forty to forty-five full and part time personnel. Cost of converting the building into a hospital facility will exceed $50,000, part of which Mr. and Mrs. Woodward will provide. The LeRoy project is planned as a model and a center for training for the various types of personnel concerned with the treatment and care of cerebral palsy patients. Opportunity will be provided for training in research at the University of Rochester School of Medicine and Dentistry, hospital care at the LeRoy unit and physical and occupational therapy. The research program is under the direction of Dr. R. Plato Schwartz, associate professor of orthopedic surgery in the Rochester Medical School. Dr. Alan Valentine, president of the university, has entered into negotiations with the state of New York regarding state financial support to cover the cost of operation of the proposed clinic over a stated period of years. Dr. Edward S. Godfrey, state health commissioner, and other advisers of Governor Dewey have worked closely with representatives of the university in planning the undertaking. Trustees of the university have offered all its pertinent resources and a special committee appointed by Dr. George H. Whipple, dean of the School of Medicine, to supervise the basic science and clinical research program. While emphasis would be placed on spastic cases, the similarity of spasticity of muscles in infantile paralysis will lead, it is hoped, to improved methods of treating victims of the latter disease in acute, convalescent and chronic stages.

New York City

Medical Center Receives Grant.—A grant of $150,000 from the New York Foundation has been received by the chairman of the $15,575,000 campaign for the New York University-Bellevue Medical Center. One-half the amount is to be applied toward the work of the new Institute of Rehabilitation and Medicine.

Women's Association Awards Medal.—A medal was presented to Dr. Elise D. S. L'Esperance, head of a cancer clinic in the New York Infirmary for Women and Children, and of a similar clinic in Memorial Hospital for the Treatment of Cancer and Allied Diseases. The medal is the 1946 award of the American Women's Association and was presented at a dinner held by forty-four business and professional women's groups.

Annual Maimonides Lecture.—The annual Maimonides lecture under the auspices of the Clinical Society of the Beth El Hospital will be presented February 13 at 8:30 p. m. at the Jewish Sanitarium and Hospital for Chronic Diseases, Rutland Road and East 49th Street, Brooklyn. The lecturer will be Dr. Chester S. Keefer, Boston, chairman of the committee of chemotherapy and other agents of the National Research Council, speaking on "Antibiotics in Clinical Medicine."

Free Cancer Detection Clinic.—Under the sponsorship of the Brooklyn Cancer Committee and with the cooperation of Dr. Edward M. Bernecker, commissioner of hospitals, a free cancer detection clinic was opened Nov. 16, 1946 in the Brooklyn Cancer Institute. The new clinic accepts only well persons. During its first week more than 250 persons requested examination, 50 per cent of whom qualified as to health and financial eligibility. Dr. Hyman I. Teperson, Brooklyn, is director of the clinic.

Notes from the Annual Report.—Some highlights of the annual report of the New York City Health Department include the following: More babies were born during 1946 than during any previous year in the city's history with both infant and maternal death rates making new all time lows; the lowest death rate in the city's history was recorded for whooping cough; the 1946 tuberculosis death rate was less than 42 per hundred thousand of population, less than the 1945 record; for the fifth successive year there was an increase in reported cases of infectious venereal diseases; approximately one half of all deaths were among persons over 60; although infantile paralysis increased throughout the country, New York City did not have an unusual number of cases.

NORTH CAROLINA

Grant for Research on Quinine.—The School of Medicine of the University of North Carolina, Chapel Hill, has accepted a grant from the Cinchona Products Institute, New York, for continuation of the work of Edwin P. Hiatt, Ph.D., on the effects of quinine and other cinchona alkaloids on renal function and blood pressure.

Course in Mycology.—Duke University School of Medicine and Hospital, Durham, will offer a month's course in medical mycology during July. The course is designed to provide a working knowledge of human pathogenic fungi. Emphasis will be placed on the practical aspects of the laboratory as an aid in helping to establish a diagnosis of fungous infection. Work with patients, clinical material, cultures and laboratory animals will serve as a basis for this course. The number of applicants will be limited, and applications will be considered in the order in which they are received. The course will be under the direction of Dr. Norman F. Conant, to whom inquiries should be addressed. The fee for the course will be $50, and on completion a suitable certificate will be awarded.

PENNSYLVANIA

Another Hundredth Anniversary.—The hundreth anniversary of the Northern Medical Association was observed Dec. 5, 1946, at a dinner meeting in Philadelphia. Dr. Richard K. Shryock, professor of American history, University of Pennsylvania, gave the main address on "The Status of the Physician: 1846-1946." The association, second oldest medical society in Philadelphia, was founded Dec. 5, 1846. The centennial committee is composed of thirty living ex-presidents.

Students of Buenos Aires Honor Dr. Jackson.—Dr. Chevalier L. Jackson, chief of the bronchoscopic department of Temple University Hospital, Philadelphia, was the recent recipient of a gold medal for his work in training South American physicians and surgeons. The medal was presented by the Argentine ambassador to the United States on behalf of the students at the University of Buenos Aires, where Dr. Jackson is an honorary faculty member, before two hundred members of the Pan American Association of Philadelphia.

Philadelphia

Personal.—Dr. Francis C. Grant, professor of neurologic surgery, University of Pennsylvania School of Medicine, addressed the Summit Medical Society, Akron, Ohio, Dec. 3, 1946, on "The Surgical Treatment of Pain."

Dr. Engel Appointed Clinical Professor.—Dr. Gibson Colby Engel was appointed professor of clinical surgery at the University of Pennsylvania Graduate School of Medicine, Dec. 20, 1946. Dr. Engel also serves as chief of Surgical Service B at Lankenau Hospital and at Children's hospital of the Mary K. Drexel Home; is a trustee of the Medical Society of the State of Pennsylvania and district medical officer for the Medical Service Association of Pennsylvania. He is a graduate of Johns Hopkins University School of Medicine, Baltimore, 1926.

TEXAS

Appoint Director of Cancer Hospital.—Dr. Randolph L. Clark Jr., Jackson, Miss., has been appointed director of the M. D. Anderson Hospital for Cancer Research in the Texas Medical Center, Houston. Dr. Clark has been on the surgical staff of the Mayo Clinic and consultant in surgery at the Mississippi State Charity Hospital, Jackson, and the Mississippi State Tuberculosis Sanatorium. He was also director of the department of surgery, AAF School of Aviation, Randolph Field, Texas, and was chief of the surgical service AAF Technical Training School.

WEST VIRGINIA

State Association Approves Proposed Legislation.—The council of the West Virginia State Medical Association has approved the enactment of legislation transferring full medical supervision of state mental and tuberculosis institutions from the board of control to the state health department. The council went on record as favoring the continued administration of the fiscal affairs of these institutions by the board of control. The council recommended the merger of city and county health units and the establishment of additional units in every county or group of counties in the state, the reorganization of the department of public assistance so as to make it possible for county offices to remain open twenty-four hours each day so that medical and hospital care for the indigent sick may be authorized promptly, and the continuance of the two year medical school at West Virginia University and the construction of modern buildings as soon as materials are available. The council advocated the enactment of a bill licensing hospitals.

WISCONSIN

Appoint Professor of History of Medicine.—Dr. Irwin H. Ackernecht has been appointed to the staff of the University of Wisconsin School of Medicine, Madison, as professor of the history of medicine. Dr. Ackernecht comes from the staff of the American Museum of Natural History, New York. Born in Stettin, Germany, in 1906, he received his degree of doctor of Medicine at the University of Leipzig in 1931 and came to the United States in 1941 as a research fellow at the Institute of the History of Medicine, Johns Hopkins University. He has contributed extensively to the literature concerning the history of medicine, and his articles have been published in German, French and English.

GENERAL

Ophthalmology Directory.—The American Board of Ophthalmology has announced that it will publish a directory of certified specialists to Jan. 1, 1947, the arrangement to be alphabetical and geographic. No biographic material will be included. Certified specialists who have not already done so should notify the American Board of Ophthalmology, Cape Cottage, Maine, stating their names and addresses exactly as they wish them listed.

Appointment of Research Director of Foundation for Infantile Paralysis.—Harry M. Weaver, Ph.D., acting director of research for the National Foundation of Infantile Paralysis, has been made director of research for the organization. Mr. Weaver is a graduate of Ohio State University, Columbus, and was an instructor in Wayne University College of Medicine, Detroit, from 1938 to 1942, when he was appointed assistant professor of anatomy.

Literary Guild Extends Its Deadline.—The Physicians' Literary Guild, an organization devoted to the nonmedical writings of doctors, has extended its deadline from January 2 to March 15 for entries in its next literary exhibition to be held at the time of the annual session of the American Medical Association in Atlantic City in June. All entries should be submitted to Dr. Francis Redewell, 526 Flood Building, San Francisco. The guild was organized in January 1946 (THE JOURNAL, March 16, 1946, p. 728) and held its first exhibition in San Francisco at the time of the American Medical Association meeting there last July (THE JOURNAL, Aug. 10, 1946, p. 1234).

New Sponsor for Occupational Therapy Magazine.—*Occupational Therapy and Rehabilitation*, for twenty-five years the official organ of the American Occupational Therapy Association, begins 1947 publication under sponsorship of the Williams and Wilkins Company, Baltimore. It will be devoted to the scientific reporting of the applications of occupational therapy and to the advances in rehabilitation and will be written primarily for and by physicians. Dr. William Rush Dunton Jr., one of the founders of the magazine, has retired as editor, and Dr. Sidney Licht, New York, has been appointed editor. Dr. Licht is a graduate of New York University College of Medicine, 1931.

Society of Vascular Surgery.—A small group met recently in Cleveland to form the Society for Vascular Surgery. Its purpose is to pool and disseminate knowledge pertaining to a subject which requires much integration from the fields of physiology, biochemistry and other basic sciences. The first meeting will be held in Atlantic City, N. J., preceding the annual session of the American Medical Association and will consist of an all day program with papers in the morning and a panel discussion in the afternoon. Officers of the new society are Drs. C. W. Alton Ochsner, New Orleans, president; Emile F. Holman, San Francisco, vice president, and J. Ross Veal, Washington, D. C., secretary.

Conference of Teachers of Clinical Radiology.—Reinstatement of the conference of Teachers of Clinical Radiology, discontinued during the war years as an annual affair, has been made by the announcement of the fourteenth annual conference meeting February 8 at the Palmer House in Chicago. The meeting will precede the Annual Congress on Medical Education and Licensure by two days. The morning session, beginning at 9:30, a round table discussion on undergraduate teaching of radiology, will be headed by radiologists prominent in the field of undergraduate teaching. The subject of the afternoon session will be postgraduate training of residents in radiology, which will be discussed by leaders of the field and be followed by a discussion period. The conference will close with a banquet Saturday evening, at which Dr. Edward H. Skinner, president, will preside.

Prize for Paper on Glaucoma.—The National Society for the Prevention of Blindness announces that papers submitted for the glaucoma prize of $500 offered in 1944 did not conform to the criteria set up by the ophthalmologic committee selected to award the prize. Therefore the prize is again offered for the most valuable original paper adding to existing knowledge in regard to the diagnosis of early glaucoma or the medical treatment of noncongestive glaucoma. The criteria may be secured by writing to the National Society for the Prevention of Blindness, 1790 Broadway, New York 19. Papers may be presented by any practicing ophthalmologist of the Western Hemisphere and may be written in English, French, German, Italian, Spanish or Portuguese. Those written in any of the last four languages should be accompanied by a summary in English. Closing date for receipt of papers is December 1947.

Premedical Conference at Louisville.—Alpha Epsilon Delta, national honorary premedical fraternity, is planning a regional conference on premedical education in cooperation with the University of Louisville for February 21-22. The program will include one session on the basic sciences and another on the social sciences and humanities in relation to premedical and medical education. It will bring together members of the faculties of the more than 100 colleges and universities in Indiana, Illinois, Kentucky, Michigan and Ohio and the members of the admissions committees of the eleven approved medical schools in these states for a discussion of problems of mutual interest. The large enrolment in the colleges of veterans who are desirous of preparing for the study of medicine and the great need for early guidance of all premedical students present problems which need serious consideration. Educators interested in attending this conference should write Dr. Hugh E. Setterfield, Ohio State University School of Medicine, Columbus 10, for further details.

Fellowship for Study of Internal Secretions.—The Ayerst, McKenna and Harrison Fellowship of $2,500, authorized by the Council of the Association for the Study of Internal Secretions at its 1946 meeting in San Francisco, will be presented for the first time at the 1947 annual meeting of the association in Atlantic City. The stipend may be renewed at the discretion of the committee on awards. Applicants for the fellowship must (1) possess the degree of doctor of philosophy or doctor of medicine or their equivalent, (2) present evidence of scientific ability as attested by studies completed or in progress and/or the recommendation of responsible individuals, (3) submit a program of proposed study, (4) indicate one or more institutions where the proposed program shall be carried out, (5) submit statements of approval from investigators with whom they propose to conduct their research and (6) serve full time if awarded a fellowship. A small amount of time may be allotted for course work or for participation in teaching, the latter purely on a voluntary basis.

International Epidemiologic Reporting Service.—The United Nations Relief and Rehabilitation Administration announced on January 3 that the current volume of its bimonthly bulletin marks the cessation by that organization of an international epidemiologic reporting service which henceforth will be carried on under the auspices of the Interim Commission of the World Health Organization. The notification of reported cases of plague, cholera, yellow fever, smallpox and other serious communicable diseases has been carried on by UNRRA through forty-five issues of the Epidemiological Information Bulletin. UNRRA has shipped during the last two years 125,000 tons of medical and sanitation supplies and this was only 60 per cent of the program. The remaining 40 per cent will be dispatched early in 1947 as part of the 600 million dollars worth of relief and rehabilitation goods still to be delivered by UNRRA. Dr. Wilbur A. Sawyer, for two and a half years director of the Health Division for UNRRA and formerly director of the International Health Division of Rockefeller Foundation, said that "it is with deep satisfaction and high expectations that the officers of the Health Division hand over their duties. At the same time they wish to express their gratitude to all those officials and organizations that have cooperated with them in this important venture in international health." The World Health Organization will continue aid to needy countries for training health personnel and in the control of tuberculosis, malaria and other diseases. Consulting doctors, nurses and other health personnel will remain as part of the UNRRA operating staff in China through March and with the displaced persons in Europe through June 1947.

LATIN AMERICA

New Medical Journal.—*Cadernos Cientificos,* the official organ of the Instituto Pasteur of Lisbon, recently appeared. Headquarters are the Instituto Pasteur de Lisboa, Rua Nova do Almada, 69.-1., Lisboa, Portugal.

Hospital News.—The Hospital de Enfermedades de la Nutricion in Mexico City was opened to the public October 12. Speakers included Dr. Salvador Zubiran, head of the hospital; Dr. Gustavo Baz, secretary of public health and public assistance of Mexico, and Manuel Avila Camacho, divisionary general, the president of Mexico.

Special Society Elections.—Dr. Edgard Magalhaes Gomes was elected president of the Brazilian Society of Cardiology during its recent meeting in Belo Horizonte. Other officers include Dr. Octavio Magahlaes, vice president; Dr. Roberto Mexenes de Oliveira, general secretary; Dr. Rinaldo Chiaverini, second secretary, and Dr. Luiz Murgel, treasurer. Correspondence should be addressed to the society of Sociedade Brasileira de Cardiologia, Av. Mem de Sa 197, Rio de Janeiro, D. F., Brazil.

Congress of Neurosurgery.—The second South American Congress of Neurosurgery will be held at Santiago, Chile, April 21 to 27, 1947. Among the subjects discussed will be (1) hydrocephalus, (2) histology of brain tumors in relation to clinical findings and (3) brain abscess. The meeting is sponsored by the Chilean government, which will grant free visas to those who wish to attend. Efforts are being made to obtain special travel rates. The registration fee is eighteen United States dollars. For further information write to Dr. Carlos Villavicencio, Institute of Neurosurgery and Neuropathology, Casilla 70 D, Santiago, Chile.

Argentine Psychologist to Study in the United States.—Dr. Horacio J. A. Rimoldi, director, Institute of Psychology, and professor of biology, University of Cuyo, Mendoza, Argentina, is visiting the United States at the invitation of the Department of State. He plans to spend a year at the University of Chicago in advanced training and research in the Psychometric Laboratory. Dr. Rimoldi, a graduate of the Faculty of the Science of Medicine of Buenos Aires, spent two years in England and did postgraduate work at Oxford. He is the founder and director of the Experimental Institute of Psychology of the University of Cuyo.

FOREIGN

Edinburgh Election.—At the annual meeting of the Royal College of Physicians of Edinburgh, Scotland, December 5, Dr. David M. Lyon was reelected president. Drs. William D. D. Small, Leybourne S. P. Davidson, James D. S. Cameron, Henry L. Wallace, Ian G. W. Hill and David K. Henderson were elected to form the council of the college for the coming year.

Cholera in India.—The government at New Delhi, India, has announced that cholera has taken a heavy toll. In the United Provinces, the announcement said, 263 deaths were recorded in the week ended December 14. Bihar province reported 257 deaths the preceding week and Bengal 672 deaths in the last week of November, although they dropped to 61 the following week.

CORRECTION

Amnesia During Parturition.—In the article by Dr. Volpitto in THE JOURNAL Dec. 28, 1946 the statement of composition at the top of the second column of page 1060 should have read "Each cubic centimeter of this dilution contains 0.025 Gm. (3/8 grain) of pentobarbital sodium and 0.000064 Gm. (1/1000 grain) of scopolamine hydrobromide."

Marriages

GAYLORD A. HART, Dallas, Texas, to Mrs. Anne Colcough Longfellow in Lamar, S. C., September 29.

EVERETT MEADE BAKER, Pittsburgh, to Miss Betty Elaine Humbert of Confluence, Pa., October 30.

DAVID M. CRAIG, Minneapolis, to Miss Carol Jean Harrin of Batesville, Ark., September 17.

JOHN JOSEPH COFFEY, Clayton, Mo., to Miss Roberta Jean Treece of Kirkwood October 26.

WILLIAM HILDEBRAND JR. to Miss Martha Jane Weaver, both of Buffalo, September 7.

Deaths

Stewart H. Welch ⊕ Birmingham, Ala.; born in Uniontown, Ala., Dec. 23, 1881; Cornell University Medical College, New York, 1907; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; chairman of the pediatric section, Southern Medical Association; past president of the Jefferson County Medical Society and the Alabama State Pediatric Society; served as assistant city health officer and as secretary of the Jefferson County Board of Censors; formerly associate professor of pediatrics at the Birmingham Medical College; for many years on the staff of the Southern Pediatric Seminar at Saluda, N. C.; pediatrician in charge of department, American Cast Iron Pipe Company; on the staffs of the Children's Hospital, Hillman Hospital, South Highlands Infirmary and Baptist Hospital, West End and Highland branches; consultant pediatrician at the St. Vincent's Hospital; died Nov. 8, 1946, aged 64, of carcinoma of the lung.

John A. McGlinn, Philadelphia; born in Philadelphia in 1871; Medico-Chirurgical College of Philadelphia, 1899; member of the American Medical Association; past president of the Philadelphia County Medical Society and of the Philadelphia Obstetrical Society; past vice president and fellow of the American Gynecological Society; served during the Spanish American War and World War I; captain in the medical corps of the U. S. Naval Reserve; formerly associate professor of gynecology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; served on the staffs of Fitzgerald-Mercy Hospital in Darby, Pa., St. Agnes Hospital, St. Joseph Hospital, St. Vincent's Hospital for Women and Children, Philadelphia General Hospital, St. Luke's and Children's Medical Center and the Graduate Hospital of the University of Pennsylvania, where he died Nov. 29, 1946, aged 75, of coronary disease and hypertension.

William Ledlie Culbert ⊕ Miami, Fla.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1888; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; an Affiliate Fellow of the American Medical Association; member of the New York Academy of Medicine; formerly practiced in New York City, where he was on the staff of the Manhattan Eye, Ear and Throat Hospital and on the consultant staff of the Hospital for Special Surgery, the Mary McClellan Hospital, Cambridge, and the Sharon (Conn.) Hospital; died in Miami Beach, Nov. 18, 1946, aged 82, of acute pyelonephritis and hypostatic pneumonia.

Samuel Barbash ⊕ Atlantic City, N. J.; Medico-Chirurgical College of Philadelphia, 1905; since 1939 a member of the New Jersey Board of Medical Examiners, serving as president in 1941-1942; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; twice president of the Atlantic County Medical Society; member of the New Jersey State Pediatric Society, Philadelphia Pediatric Society, American Heart Association and the American Congress of Physical Therapy; medical director of the Atlantic City Hospital; died Nov. 14, 1946, aged 62, of coronary thrombosis.

Enga Mitchell Arnold ⊕ Houston, Texas; University of Texas School of Medicine, Galveston, 1907; served as vice president of the Harris County Medical Society and past president of the Houston Eye, Ear, Nose and Throat Society; served overseas during World War I; on the board of the Veterans Administration; on the staffs of the Hermann Hospital, Methodist Hospital, St. Joseph's Hospital and the Southern Pacific Hospital, where he died Nov. 1, 1946, aged 64, of heart disease and hypertension.

Jesse Oscar Bailiff, Mullens, W. Va.; Chicago College of Medicine and Surgery, 1914; member of the American Medical Association; served during World War I and as a member of the state legislature; died Nov. 3, 1946, aged 61, of hypertension.

John A. Bauer, Columbus, Ohio; Ohio Medical University, Columbus, 1894; member of the Columbus Academy of Medicine; died in the Mount Carmel Hospital Nov. 21, 1946, aged 83, of bronchopneumonia and rheumatic heart disease.

Edwin P. Becton ⊕ Greenville, Texas; University of Tennessee Medical Department, Nashville, 1902; past president of the Hunt County Medical Society; served as a member of the state board of medical examiners; vice president and director of the Greenville National Exchange Bank; medical director and owner of the Dr. E. P. Becton Hospital; died recently, aged 68, of hypertension and arthritis.

Clifton LeRoy Belding ⊕ Itasca, Ill.; Northwestern University Medical School, Chicago, 1911; on the staff of the Bethany Home Hospital, Chicago; formerly professor of ophthalmology at the Illinois Post-Graduate Medical School in Chicago; died Nov. 11, 1946, aged 61, of coronary thrombosis.

Bernard John Bertram, Algoma, Wis.; Marquette University School of Medicine, Milwaukee, 1937; member of the American Medical Association; interned at St. Mary's Hospital in Milwaukee; served as president of the Algoma Junior Chamber of Commerce and as director of the Chamber of Commerce; died Oct. 30, 1946, aged 34, of melanosarcoma.

Walter Clinton Bisson, Charleston, Ill.; Chicago Homeopathic Medical College, 1903; served in France during World War I and as postmaster of Charleston; died Oct. 1, 1946, aged 71.

M. L. Bridge, Van Buren, Ind.; Rush Medical College, Chicago, 1896; served on the staff of the Marion (Ind.) General Hospital; died Nov. 3, 1946, aged 76, of cerebral hemorrhage.

Cyril Joseph Byrne, Lowell, Mass.; Middlesex College of Medicine and Surgery, Waltham, 1936; found dead in bed, Nov. 12, 1946, aged 38.

Allen Vincent Carl ⊕ Danville, Pa.; Medico-Chirurgical College of Philadelphia, 1909; served during World War I, as Danville borough school physician and as medical director of Montour County; died in the Geisinger Hospital Nov. 20, 1946, aged 62, of coronary occlusion.

Henry D. Champlin, Fort Myers, Fla.; Homeopathic Hospital College, Cleveland, 1882; Cleveland College of Physicians and Surgeons, 1899; served as professor of nervous diseases at the Cleveland Medical College and on the staff of the City Hospital in Cleveland; died Nov. 13, 1946, aged 93.

Ray E. Dean, Three Rivers, Mich.; Hospital College of Medicine, Louisville, Ky., 1907; on the staff of the Three Rivers Hospital; died Nov. 4, 1946, aged 67, of coronary thrombosis.

Grace Dewey, Jacksonville, Ill.; Johns Hopkins University School of Medicine, Baltimore, 1903; served as secretary of the first board of trustees of the Morgan County Tuberculosis Sanatorium; one of the founders of the Morgan County Tuberculosis League; first woman trustee of Illinois College, where she was a member of the board at the time of her death; served on the staff of Passavant Memorial Hospital, where she died Nov. 24, 1946, aged 83, of heart disease.

Fred Counselman Dilley ⊕ Brazil, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1898; past president of the Clay County Medical Society; served during World War I and as secretary of the city board of health; on the staff of the Clay County Hospital; died Nov. 2, 1946, aged 70, of coronary occlusion.

Martin Downey ⊕ New York; Bellevue Hospital Medical College, New York, 1893; died Nov. 4, 1946, aged 80, of carcinoma.

Joseph Achille Duclos, Osceola, Wis.; School of Medicine and Surgery of Montreal, Que., Canada, 1898; died Nov. 11, 1946, aged 74, of pneumonia.

William Vincent Flynn, Hudson Falls, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1943; interned at St. Peter's Hospital in Albany; diplomate of the National Board of Medical Examiners; began active duty in the medical corps, Army of the United States, in January 1944 and service terminated in January 1946; killed Nov. 4, 1946, aged 30, in an automobile accident.

James Alexander Gaharan, Olla, La.; College of Physicians and Surgeons, Little Rock, 1909; served for many years as parish coroner; died Nov. 13, 1946, aged 71.

Morris Louis Harris ⊕ Brooklyn; University and Bellevue Hospital Medical College, New York, 1909; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; on the staff of Israel Zion Hospital; served on the staff of Long Beach (N. Y.) Hospital; died Nov. 28, 1946, aged 59, of coronary thrombosis.

Herman Everett Heacker, Oliver Springs, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1915; served as mayor and on the staff of Harriman (Tenn.) Hospital; died Oct. 30, 1946, aged 60, of heart disease.

Joseph Hubert Horton ⊕ Burnside, Ky.; University of Louisville School of Medicine, 1932; interned at St. Joseph's Hospital in Lexington; past president of the Pulaski County Medical Society; on the staffs of the Somerset City Hospital, Somerset, and the Marymount Hospital in London; died Oct. 14, 1946, aged 45, of coronary thrombosis.

Jesse Burket Howe ⊕ Erie, Pa.; Jefferson Medical College of Philadelphia, 1907; member of the staffs of St. Vincent's and Hamot hospitals; died Nov. 9, 1946, aged 64, of cerebral hemorrhage.

James Alton Humphrey, Monroe, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1908; lieutenant colonel in the National Guard; served during World War I; died Oct. 14, 1946, aged 64, of coronary thrombosis.

Frederick Henry Kuegle, Janesville, Wis.; John A. Creighton Medical College, Omaha, 1905; member of the American Medical Association and the Radiological Society of North America; specialist certified by the American Board of Radiology; served during World War I and on the staff of Municipal Hospital; died Nov. 12, 1946, aged 68, of cardiac failure.

Walter William Lang ⊕ Kalamazoo, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1905; on the staffs of the Borgess and Bronson Methodist hospitals; died Nov. 4, 1946, aged 66, of carcinoma of the stomach.

Martin Liling, New York; Fordham University School of Medicine, New York, 1914; member of the American Medical Association; died Sept. 30, 1946, aged 61.

John Henry Luikart, Moundsville, W. Va.; Ohio State University College of Medicine, Columbus, 1916; member of the American Medical Association; served on the staff of Reynolds Memorial Hospital, Glen Dale; died Nov. 9, 1946, aged 64, of cerebral hemorrhage and chronic interstitial nephritis.

Frank J. Moloney ⊕ Sault Ste Marie, Mich.; Michigan College of Medicine and Surgery, Detroit, 1899; past president of the Chippewa Mackinac Counties Medical Society; for many years industrial surgeon for the Union Carbide Company; served on the staff of the Chippewa County War Memorial Hospital; died in Detroit Nov. 23, 1946, aged 75, of cerebral arteriosclerosis and x-ray burns on the hand.

Ezra Franklin Mertz, Concrete, Wash.; Rush Medical College, Chicago, 1906; member of the American Medical Association; served during World War I; died in Sedro-Woolley Oct. 10, 1946, aged 73, of hypostatic pneumonia following exhaustion from exposure.

William S. Miller, Uniontown, Kan.; American Medical College, St. Louis, 1886; died Nov. 4, 1946, aged 86, of senility.

Alvin Thomas Nelson, Wrangell, Alaska; University of Nebraska College of Medicine, Omaha, 1941; diplomate of the National Board of Medical Examiners; served an internship and residency at the Hurley Hospital in Flint; served a residency at the Henry Ford Hospital in Detroit; served in the medical corps of the Army of the United States from June 1944 to April 1945, when he was relieved from active duty; killed in a hunting accident in October 1946, aged 41.

Asa Burton Nichols, Norwood, Ohio; the Hahnemann Medical College, Chicago, 1895; died Sept. 27, 1946, aged 74, of pneumonia.

Adolph Nicholas Nittler ⊕ Santa Cruz, Calif.; Oakland College of Medicine and Surgery, Oakland, 1909; served as county health officer and as president of the Santa Cruz Hospital; died Oct. 10, 1946, aged 60, of chronic rheumatic endocarditis and chronic parenchymatous nephritis.

Henry O. Ogden, Mechanicsburg, Ohio; Eclectic Medical Institute, Cincinnati, 1903; died in a hospital in Columbus Nov. 17, 1946, aged 73, of pneumonia following an operation.

Robert Child Paine ⊕ Thompson, Conn.; Dartmouth Medical School, Hanover, N. H., 1900; past president of the Windham County Medical Society; served as councilor of the Connecticut State Medical Society; since 1930 president and since 1900 member of the staff of the Day Kimball Hospital, Putnam, where he died Nov. 7, 1946, aged 72, of coronary thrombosis.

Maud Ferguson Pratt, Springbrook, Wis.; Milwaukee Medical College, 1909; formerly connected with the state hospitals in Independence, Iowa, Mendota and various others; died in the Wisconsin General Hospital in Madison, Oct. 28, 1946, aged 74, of peritonitis secondary to ruptured diverticulum of the descending colon.

Lawrence Hort Prince, Kiln, Miss.; Rush Medical College, Chicago, 1885; fellow of the American College of Surgeons; at one time attending obstetrician at the Augustana Hospital in Chicago; formerly associated with the Palmyra Springs Sanitarium in Palmyra, Wis., and the Waukesha Springs Sanitarium in Waukesha; served as school physician for the board of education in Madison and as superintendent of the Wisconsin State School of Dependent and Neglected Children at Sparta; died Nov. 29, 1946, aged 87.

Gustave H. Reinhardt, Mira Loma, Calif.; Washington University School of Medicine, St. Louis, 1907; contract surgeon for the U. S. Army stationed at the Mira Loma Quartermaster Depot; died in Camp Haan (Calif.) Hospital Feb. 5, 1946, aged 65, of coronary thrombosis.

Paul Roth ⊕ Battle Creek, Mich.; American Medical Missionary College, Battle Creek and Chicago, 1904; fellow of the American College of Physicians; member of the American Society of Clinical Pathologists: conducted research on basic and metabolic apparatus; served as chief of laboratories of the Battle Creek Sanitarium, where he died Nov. 7, 1946, aged 75, of cerebral hemorrhage.

Edwin M. Smith Sr. ⊕ Chicago; Chicago Medical College, 1886; on the staff of the Henrotin Hospital; died Oct. 30, 1946, aged 85, of coronary thrombosis.

Benjamin Franklin Suffron ⊕ Dayton, Ohio; University of Cincinnati College of Medicine, 1919; died Nov. 11, 1946, aged 51, of coronary thrombosis.

J. Ernest Taylor ⊕ Latham, Tenn.; (licensed in Tennessee in 1912); died in Murray, Ky., Oct. 13, 1946, aged 61.

Edmund Hershey Teeter ⊕ Jacksonville, Fla.; University of Maryland School of Medicine, Baltimore, 1910; fellow of the American College of Surgeons; on the staffs of St. Luke's and St. Vincent's hospitals; died in Chambersburg, Pa., Nov. 3, 1946, aged 64, of carcinoma of the stomach.

James Isaac Thompson, Yellville, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1892; member of the American Medical Association; died Sept. 11, 1946, aged 88.

Irving Niles Tilden ⊕ Mattapoisett, Mass.; Harvard Medical School, Boston, 1899; past president and vice president of Mattapoisett Improvement Association and a member of its executive committee since its founding in 1904; a trustee of Mattapoisett Public Library; for many years a member of the board of health; served as vice president of Plymouth County Health Association; died in the New England Baptist Hospital, Boston, Nov. 3, 1946, aged 75, of carcinoma of the bladder.

Joseph Patrick Tynan, Boston; Tufts College Medical School, Boston, 1910; died Oct. 10, 1946, aged 62, of congestive heart disease.

William Edgar Van Cleave, McAlester, Okla.; Kentucky University Medical Department, Louisville, 1905; member of the American Medical Association; for thirty-five years connected with the Indian Service, retiring in November 1942; for twenty years superintendent of the Indian hospital at Talihina, where he spent twenty-five years; died in the Albert Pike Hospital, Oct. 23, 1946, aged 69, of coronary thrombosis.

George William Walker ⊕ Cape Girardeau, Mo.; Washington University School of Medicine, St. Louis, 1903; fellow of the American College of Surgeons; served on the board of education; on the staffs of the Southeast Missouri and St. Francis hospitals; died Nov. 13, 1946, aged 70, of myocarditis.

Frank Bryant West, Lothian, Md.; Medical College of Virginia, Richmond, 1926; served during World War I; died in the Emergency Hospital, Annapolis, Nov. 19, 1946, aged 48, of injuries received in an automobile accident.

Henry Walker West, Yates Center, Kan.; Louisville (Ky.) Medical College, 1880; member of the American Medical Association; died Nov. 15, 1946, aged 90, of generalized arteriosclerosis.

Anna Louisa Wilson, Chicago; the Hahnemann Medical College and Hospital, Chicago, 1894; died Oct. 27, 1946, aged 77, of chronic myocarditis.

Roy Edward Wilson ⊕ Denver; Homeopathic Medical College of Missouri, St. Louis, 1897; served during World War I; on the honorary staff of the Presbyterian Hospital; member of the staff of St. Joseph's Hospital; formerly secretary of the Lewis County (Mo.) Board of Health; died Oct. 7, 1946, aged 71, of coronary thrombosis.

Alfred Arthur Womack, Little Rock, Ark.; Meharry Medical College, Nashville, Tenn., 1905; died in October 1946, aged 65.

Cecil Sentell Yarbrough, Auburn, Ala.; University of Tennessee Medical Department, Nashville, 1901; member of the American Medical Association; served as a member of the state legislature and as mayor of Auburn; died October 26, 1946, aged 68, of heart disease.

James Archibald Young, Maysville, Okla. (licensed by years of practice); died in a hospital at Pauls Valley in October, aged 83.

Result of the Plebiscite Taken by the British Medical Association

As reported in a previous letter to THE JOURNAL, the British Medical Association took a plebiscite of the whole medical profession, nonmembers as well as members, on the question whether to negotiate or to refuse to negotiate with the government on the National Health Service Act. The result has now been declared. The number of voting forms sent out totaled 56,871½. The voting was 18,972 in favor of negotiation and 23,110 against. Thus 14,589 forms had not been returned, but some are still coming in. The council of the British Medical Association has decided that the majority against negotiation is sufficient to put the following resolution to a special meeting of the Representative Body to be held on January 28: "That the negotiating committee be advised that, in view of the results of the plebiscite, the minister be informed that, because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the committee is unable to enter into discussions on the regulations to be made under the act."

The biggest majority against negotiation came from general practitioners and specialist groups. For general practitioners the figures were 6,375 in favor of negotiation and 11,297 against. The position was reversed among doctors in whole time salaried service: 3,791 for negotiation and 2,021 against. Of the consultants and specialists in England and Wales 1,884 voted Yes and 2,106 No. Doctors in the fighting services voted Yes by 56 to 44 per cent.

The minister of health, Mr. Bevan, has issued a statement to the press that he has learned that the British Medical Association is placing the result of the plebiscite before a special representative meeting with a recommendation that the profession should refuse to discuss the steps to be taken to bring the National Health Service into operation. He hopes that before any final decision is taken accepting this recommendation wiser counsel will have prevailed, and he feels sure that the medical profession will take no steps which would make it difficult for physicians to take part in the comprehensive health service which the people of the country so ardently desire. Meanwhile, he says, he has a clear duty to carry out the instructions of Parliament as expressed in the act, and he can no longer postpone the consultations preliminary to setting up the administrative machinery. He therefore proposes to consult all the many other interests concerned. He is also considering what ought to be done to give the medical profession the opportunity of assisting to shape, and of playing its part in the new service. A struggle between the government and the British Medical Association thus seems imminent.

The Royal College of Surgeons

The report of the Royal College of Surgeons for the first postwar year, 1945-1946, shows the work done in restoration after the destruction due to German bombing. By last June all the anatomic specimens which had been evacuated to dispersal centers had been brought back. Most of them were in good condition, although the dampness had damaged some. But examination of the specimens which had survived bombing of the college revealed great losses which can be made good only by years of heavy work. This work cannot start until the department has been repaired and reequipped.

The work on malnutrition done under Dr. John Beattie, research professor of the college in western Netherlands and Germany, has yielded important results. It was shown that heat loss is regulated by nervous control of the vessels of the skin, while heat production, under conditions of rest, is controlled mainly by the endocrines, which in turn may be influenced by nervous mechanisms. In the conditions of starvation found in western Netherlands the body temperature became stabilized at a low level but the diurnal variations often exceeded the normal. For the optimum rate of growth the calory intake must be constantly related to the nitrogen intake. If the nitrogen intake is doubled, calory intake must also be doubled to conserve as much as possible of the nitrogen. The work in Germany showed that hunger edema is not, as was thought, due merely to hypoproteinemia but apparently results from a specific defect in the kidney due to deficient diet.

NEW ZEALAND ENDOWMENT

A New Zealand industrialist who wishes to remain anonymous has made a gift to the college for the endowment of a "commonwealth traveling professorship." The endowment provides an income of $8,000 a year. A commonwealth professor will be appointed each year and will generally be a physician, surgeon or scientific worker resident in Britain, Australia or New Zealand, but a distinguished teacher from one of the other dominions may also be appointed. The professor will be required to travel to Britain, Australia, New Zealand or any other dominion to assist in the advancement of medical science by lecturing, teaching or research. The president of the Royal College of Surgeons in announcing the gift said that although it had been made to the college the donor wanted representatives of other bodies to help in the appointing. This gift has excited considerable interest and has been described by the prime minister as a munificent and far sighted gesture showing "real appreciation of the needs of medicine, science and the British commonwealth."

Helen Keller Praises the British National Institute for the Blind

Dr. Helen Keller, the deaf and blind authoress whose successful struggle against the disabilities with which she was born is almost incredible, has just completed a visit to this country. In a farewell message to the National Institute of the Blind she stated that Britain was rallying quickly and energetically from its war catastrophe. Full of confidence, she looked to England to be an Elijah to its noble creation the National Institute for the Blind and to pour on it a double portion of its reborn vitality. Having known the institute during almost a lifetime, she dared to say that it shone among the foremost beacons of true civilization. Its story was a magnificent record of unremitting effort to reintegrate the broken lives of the blind throughout the empire and indeed the world.

The Highest Birth Rate for Twenty-Three Years

The improvement in vital statistics often reported in THE JOURNAL during the war continues. The highest birth rate in any quarter since June 1923 is recorded for the September quarter of 1946, when there were 213,135 live births, representing a birth rate of 19.7 per thousand of population. The upward trend shown in the June quarter, when the number of births was 203,797, is thus maintained. The birth rate of 19.7 is 4.1 above that for the third quarter of 1945 and 4.5 above that for the corresponding quarter of 1938, the last complete prewar year. The average for the September quarters of the years 1940-1944 was 15.4.

An Airborne Medical Society

An Airborne Medical Society has been formed. Membership is open to all medical and dental officers who are eligible for membership of the Airborne Forces Club. This, in fact, includes all medical and dental practitioners who are eligible for membership of the Airborne Forces Club, which means all medical and dental practitioners whose work it was or is to go to war by parachute or glider. Quartermasters and transport officers of airborne field ambulances are also eligible. Application forms can be obtained from the honorary secretary, Airborne Medical Society, 63a Belsize Park Gardens, London N. W. 3.

PARIS

Dec. 27, 1946.

Fiftieth Anniversary of Pasteur's Death

The celebration of the fiftieth anniversary of the death of Louis Pasteur, organized by the National Union of Intellectuals, has been a great event in France. The representatives of twenty-three countries, invited by the French government, were present; among those were the Professors Miss Bliss, Clark, Cori, Heidelberger, Lipmann, Perrin-Lang, Stanley and Wexman for the United States, Professors Bawden, Bernal, Buttle, Chain, Colonel Brook, Felix, Fildes, Fleming, Florey, Galle, Grieg, Knight, Morgan, Miss Stephenson, Thornton and van Heyningen for Great Britain, and Professors Engelhardt, Pavlovski, Sbarski, Parnas, Judine, Braunstein and Soloviev for Russia. At a solemn sitting of the Academy of Medicine, Roussy, dean of the Paris University, outlined the work of Pasteur, who had been a member since 1873. In an address entitled "Pasteur, a Precursor," Professor Pasteur Valery-Radot, member of the Academy of Medicine and of the institute and grandson of Pasteur, emphasized the driving power of the latter: "It was the most audacious imagination, together with intuition, which is the distinctive mark of genius, to which was associated the will to subject himself to the most patient of work. Thanks to his genius, Pasteur was able to foresee discoveries which came to light years after: filtrable germs, carriers of germs, microbian antagonism." In 1880, in a letter addressed to Dumas, Pasteur wrote "Contrary to the previsions which I just mentioned it could be possible that hens vaccinated against cholera might be refractory to anthrax; this would mean an anthrax immunity created on an animal by means of a parasitic disease of quite another nature. If this result is confirmed, and especially if it extends to other virulent diseases, it will be possible to hope for the most important therapeutic consequences even as regards the pathology of virulent diseases proper to man." A congress of pasteurian sciences was held at the Collège de France from the 19th to the 22d of November and it demonstrated the development of pasteurian ideas in the world. Among others, Professor Engelhardt of Russia spoke on Pasteur's influence regarding the biochemical phenomena, Professor Judine of Russia on antisepsis and asepsis, Professor Galloway of Great Britain on the veterinary diseases, Professor Winge of Denmark on yeasts, Professor da Fonseca of Brazil on tropical diseases, Professor Heidelberger of the United States on immunity, Professor Malenotti of Italy on insect diseases, Stanley of the United States on virus and bacteriophages and Professor Chain of Great Britain on antibiotic substances. In all these addresses the scientists demonstrated that pasteurian ideas were the starting point of numerous discoveries in several fields of medicine and biology. In the course of a ceremony presided over by Professor Joliot-Curie assisted by Jacques Trefouel, director of the Pasteur Institute, and Georges Teissier, director of the National Center for Scientific Research, Jean Painlevé showed his new film on the life of Pasteur. The members of the international congress visited Dôle, native town of the great scientist and where he got the inspiration for his works on fermentation. The periodical *Le Médecin Français* dedicated a special number to Pasteur, in which, among other articles, Trefouel wrote a paper entitled The Pasteur Institute: Realization and Continuation of Pasteurian Thought. "There is a total community of existence between the Pasteur Institute and its associated organizations, the direct continuous relations between the Paris laboratories and those overseas having a twofold interest: The Pasteur Institute receives from our colonies a constant documentation on all questions of interest and maintains a constant liaison between all the colonies, which, in their turn, benefit directly by the acquisitions of the metropolis." Academic and public ceremonies took place at Lyons and Marseilles, where Professors Lipmann, Engelhardt and Sbarski were guests, in Caen with Professor Heidelberger, at Nancy and Strasbourg with Professor Cruz-Coke of Chile and at Bordeaux and Perigueux with Professor Patocka of Czechoslovakia.

The Pasteur Exhibition

An exhibition under the auspices of Unesco was presented at the Palace of Discovery. There were autograph letters, original documents and collections relating to the scientific work of Pasteur; among others on the molecular dissymmetry of natural organic products (1847-1856), fermentation (1857) and the discovery of anaerobia (1861), studies on wine and its diseases, the method of pasteurization (1862-1871), diseases of silkworms and their treatment (1865-1867), theory of germs, anthrax, Vibrion septique (1877-1880), the discovery of vaccine virus (1879-1883) and the discovery of antirabic vaccination. The exhibition showed the revolution stirred up by Pasteur's discoveries in chemistry, industry, agriculture, surgery, medicine and hygiene and, at last, the work done by the nineteen institutes and laboratories overseas from the one of Saigon (created in 1891) to the one of Cayenne (French Guiana), created in 1940.

BELGIUM

(From Our Regular Correspondent)

Dec. 11, 1946.

International Committee of Military Medicine

Attention has been called on several occasions to the scientific and professional activities of the International Committee of Military Medicine. Since the liberation of Europe, this committee has resumed all its activities: the office of documentation, and the central organ of army physicians, of the colonies and of public health, which functions as before 1940. Its bulletin is published regularly. This committee is an intergovernmental organization, founded in 1920 by the Belgian government, to which are affiliated the health services of the armies through the Ministries of Foreign Affairs of each country. Its aim is, in the spirit of the Convention of Geneva and under the sign of the International Red Cross, to maintain and draw closer the bonds of professional collaboration between the men whose mission it is to aid the sick and wounded in the armies.

Since resuming activities, the committee has again contacted more than twenty-two countries, and the Swiss government has decided to call a general meeting in Basel for June 7, 1947. This congress, which is open to all regular and reserve officers of the health services of the armies of land, sea and air, of the colonies and of public health, will take up the following questions: *Methods of Resuscitation of the Wounded* (Reporting countries: France, Great Britain and Yugoslavia); *Prophylactic Procedures Against Epidemic Diseases in Armies* (Reporting countries: United States, Great Britain and Switzerland); *Methods of Evacuation of the Wounded and Sick: Indications and Contraindications* (Reporting countries: Canada, Poland and Union of Soviet Socialist Republics); *Role of Military Physicians in Maintaining the Morale and Physical Condition of Soldiers* (Reporting countries: Belgium, France and Switzerland), and *Study of Methods and Apparatus for Determination of Hydrogen Ion Concentration in View of Their Employment in the Pharmaceutical Laboratories of Armies* (Reporting countries: Brazil, France and Switzerland).

The conclusions on every question will be transmitted to all governments by the committee. Besides these activities, the International Committee of Military Medicine, since 1934, has studied the question of the revision of the International Humanitarian Conventions and their fusion into a single document. As a result of numerous meetings of experts and in the light of new war experiences a preliminary conference has been held in Geneva to study this project. The International Committee of the Red Cross, basing its study on the numerous works of the medicolegal commissions of the International Office of Military Medicine, has prepared a vast project of trying to unify and coordinate all conventions in existence at present.

In the framework of the Office of the United Nations it is evident that an intergovernmental organization such as the International Committee of Military Medicine can render great service by the relations which have been established between armies by the exchange of their health services.

Station of Reeducation and Apprenticeship

Dr. Derscheid presented to the Belgian Society for the Scientific Study of Tuberculosis a discussion of the rehabilitation of tuberculous patients for work, inspired by the results of the school at Marcinelle. A statistical report of 1,679 grave or chronic cases indicated that after sanatorium treatment followed by a period of retraining one third of the patients could resume light or part time work. Sixty-seven per cent of patients with a mild form of the disease improved enough to return home and resumed their former occupation. Of these 91.4 per cent have continued their work after one year. Of the 33 per cent who did not take up their old work and acquired a new occupation, the proportion of those still maintaining themselves after a year was 73.7 per cent. In the readaptation to work the balance is thus in favor of the patients who have resumed their former occupation

Peptic Ulcer and Nutritional Deficiencies

Dauwe in the *Bulletin International des Services de Santé des Armées* presented a study of the frequency of peptic ulcer during the German occupation and found that the number of gastric and duodenal ulcers increased greatly. Statistics of the Service of Internal Medicine of the University of Ghent proved this. He cites the experience of Silbermann, who by inducing an esophageal fistula in dogs produced a severe gastric hypersecretion by a conditioned reflex, and at the same time he prevented food from reaching the stomach. In the same way, repeated injections of histamine into a fasting animal produced gastric hypersecretion. In both conditions ulcers appeared. In case of starvation people find themselves somewhat in the condition produced experimentally by Silbermann. Presumably many people would not have developed ulcer if they could have eaten as usual.

Medical Meeting in Brussels

The twentieth session of the Medical Days of Brussels provided a varied program and was attended by nearly 1,200 foreign and Belgian physicians. Among the chief subjects discussed may be mentioned corneal grafting by Professor Franceschetti of Geneva at the Institute Coppez; the radiologic train of the National Society of the French Railroads; electric shock and psychophysiologic regulations; the work test and the study of its application at the obstetric clinic in Geneva; surgery of the splanchnic nerves; and penicillin.

OSLO

(From a Special Correspondent)

Jan. 8, 1947.

Medical Education in Norway

Long before the outbreak of the war, plans were being discussed for bringing the education of the medical student up to the level of modern requirements. In 1939 the Faculty of Medicine adopted a new plan, but it never materialized owing to the German occupation. Now discussions have been resumed, and on Nov. 20, 1946 there was a full dress debate on the subject at the headquarters of the Norwegian Medical Society in Oslo. One speaker, Professor Johan Holst, urged the speeding up of education from childhood, school to be started at the age of 6 instead of 7, the university to be entered at the age of 17, and the final examinations to be passed at the age of 23. Another speaker pointed out how ill equipped the university is with teachers; while in Sweden there is one teacher to every eight or nine students, in Norway there is only one to every fifteen students. A senior medical student, invited to voice the feelings of his contemporaries, branded as a fundamental evil the intensive cramming which elbows out practical training. The remedies he proposed for this evil included a wider distribution of medical students in various hospital departments, a critical revision of the curriculum and a simplification of the system of marks. He would like to see students housed and fed free of charge in the hospitals they attend and fees for courses and examinations paid by others. Professor Axel Ström gave an account of a recent visit to the United States, with special reference to medical education in this country. The large attendance at this meeting was plain evidence of the great interest taken in the reform of the medical curriculum in Norway.

An Experiment in Dental Hygiene

In 1938 the municipal authorities in Oslo started a health demonstration in the northern quarter of the town with a population of some 70,000. A group of doctors, dentists and nurses, as well as experts in household economy and gymnastics, carried out various activities on behalf of mothers and children. Here reference will be confined to a survey of dental caries based on quarterly examinations of all the children in the district from the age of 18 months to 7 years. They were given a diet planned to eliminate as much as possible easily fermenting carbohydrates likely to promote acid conditions in the mouth. The mothers were also instructed in local dental hygiene. The children were classed in two groups according to whether they had or had not enjoyed the benefits of the health demonstration before they were 12 months old. A comparison showed that dental caries was about 50 per cent less extensive in certain age groups among the children under the influence of the health demonstration than in the control group.

Research into the Nature of Dental Caries

The German occupation of Norway created certain conditions remarkably favorable for the study of dental caries. Not only were there profound changes in the nation's dietary, but the much restricted food supplies were also weighed and measured as never before. The Norwegian Association for the Care of the Teeth has recently offered a prize for the best essay dealing with the causes of the decline of dental caries during the second world war as studied in Norway. It is proposed that the winner shall be awarded the first prize of 3,000 kroner while the runner-up is to receive 2,000 kroner. There are to be three judges, one to be selected by the Faculty of Medicine of the University of Oslo, one by the Norwegian Dental High School and one by the Norwegian Association for the Care of the Teeth. The competition will be closed on September 1.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D. D. N. J. and foods, F. N. J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Ademo Tablets.—Ademo Corporation of America, Los Angeles. Shipped between March 2 and June 8, 1943. Composition: Essentially as stated on label, namely: "Formulated from the Active Principle of Violet Ray Treated (Red Blood Cell Building) fraction of Desiccated Raw Liver Extractive, Iron, Special Type Yeast, Concentrated Hemoglobin (Blood Powder), Milk Whey, Chlorophyll, Plus the following for each 6 tablets: H. P. Thiamin (B-1 . . . 1200 I. U. H. P. Riboflavin (B-2 . . . 3000 Micrograms Niacin . . . 10,000 Micrograms Iron . . . 20.24 Milligrams. Also minerals containing trace elements of Calcium, Chlorine, Magnesium, Sulphur, Potassium, Phosphorus and Pantothenic Acid as Naturally found in Yeast and Liver." One lot misbranded because label and accompanying display card falsely represented that preparation would build blood, strength, energy and vibrant health. Another lot misbranded for this reason, and because represented to correct rapid heart beat, infections, neuritis, nerve disease, beriberi, depression, loss of weight, intestinal disorders, pellagra, gingivitis, dermatitis and many other disorders.—[*D. D. N. J., F. D. C. 1122; June 1945.*] Both lots also misbranded under provisions of the law applicable to foods.

Bates Vitamin Preparations.—Bates Laboratories, Inc., Chicago. Shipped between Feb. 2 and March 20, 1943. Composition: government chemists' report indicated that it largely conformed to that represented by the products' names: Bates Natural B Complex, Bates Riboflavin Vitamin B_2 (G), Bates (Thiamine) Vitamin B_1, Bates (Nicotinic Acid) Niacin, Bates (Ascorbic Acid) Vitamin C, Bates Vitamin A & D, and Bates Calcium Pantothenate. All misbranded because accompanying literature falsely suggested that the products, singly or together, were effective treatments for loss of weight or appetite, bleeding gums, nutritional, nervous or skin disorders, indigestion, gray hair, anemia, blindness, atrophy of glands, and many other conditions.—[*D. D. N. J., F. D. C. 1128; June 1945.*] Also misbranded under provisions of the law applicable to foods.

Curley Bu-T-Caps Vitamins.—Curley Distributing Company, Philadelphia. Shipped April 21, 1943. Composition not reported. Misbranded because literature accompanying package falsely represented product as effective in insuring good health, beauty and good complexion, preventing or correcting poor teeth, retarded growth, liver and kidney ailments, body malformation, anemia, neuritis, beriberi, pellagra, certain heart disorders, rickets, scurvy and some other conditions.—[*D. D. N. J., F. D. C. 1123; June 1945.*]

Curley Cal-Pans Vitamins.—Curley Distributing Company, Philadelphia. Shipped April 21, 1943. Composition not reported. Misbranded because literature accompanying package falsely represented that product was effective in preventing graying of hair or restoring natural color to gray hair.—[*D. D. N. J., F. D. C. 1123; June 1945.*]

DPS Formulae.—Dartell Laboratories, Los Angeles. Shipped between March 23 and May 8, 1943. DPS Formula 52 claimed on label to consist of fish liver oil concentrate, wheat germ oil, mixed natural tocopherols, treated linseed oil containing the fatty unsaturates and soya oil containing lecithin. Misbranded because label falsely represented product to be useful in impotency, menopause, anterior pituitary deficiency and tendency to abort. DPS Formula 57 label claimed composition to be fish liver oil concentrate, dehydrated garlic and alfalfa, lac-sulfur and chlorophyll. Misbranded because label falsely represented product as effective treatment for hypertension, toxic conditions and bowel putrefaction. DPS Formula 58 label claimed composition to be powdered kelp, dicalcium phosphate, fish liver oil concentrate, yeast, rice polishings and wheat germ. Misbranded because of label misrepresentations that article would effectively treat lowered fat and protein metabolism, low basal metabolic rate, thyroid deficiency, low calcium metabolism, pregnancy and lactation, obesity, and disorders of the nerves and skin. DPS Formula 61 label gave ingredients as mixed natural tocopherols and wheat germ oil, and falsely represented product's efficacy in sterility, mental dullness, poor skin, weakness of female organs, paralysis, and lack of motility of eye lens. DPS Formula 66 label declared presence of unsaturated fatty oils naturally present in wheat germ oil and fish liver concentrate, besides special high potency vitamin A. Label falsely represented usefulness for sinusitis, catarrh, asthma, colds, otitis media, mucous infections and eye disorders. DPS Formula 81 label declared presence of 2.6 milligrams of the sodium copper soluble salt of chlorophyll, and falsely represented product's efficacy for hypertension, cardiovascular conditions, toxic conditions, impaired cellular respiration, anemias and infections. DPS Formula 100 label declared presence of iron sulfate, desiccated liver, hog stomach substance, pepsin, spleen substance, red bone marrow, kelp, hemoglobin, and vitamins B_1, B_2 and C. Label falsely represented product to be efficacious in anemias, toxic changes in blood, fatigue, low blood pressure, underweight, pregnancy, and some other conditions. DPS Formula 103 label declared that these tablets provided 4,000 International Units of vitamin A, and 5 milligrams vitamin E in a base of these inert desiccated glandular substances: Anterior pituitary, whole ovarian, ovarian residue, and adrenal cortex. Misbranded because label falsely represented product's efficacy for scanty or difficult menstruation, anemia, dysmenorrhea, delayed puberty, delayed menstruation, painful breasts, hot flashes, menopause, ovariectomy and sexual asthenia. DPS Formula 105 label declared presence of I. U. vitamin A and vitamin E in a base of these inert desiccated glandular substances: orchic, prostate, whole adrenal, anterior pituitary and suprarenal cortex. Label falsely represented that product would effectively treat impotency, sterility, lowered sex-tone, apathy and mental lethargy.—[*D. D. N. J., F. D. C. 1124; June 1945.*] DPS Formulae 52, 57, 58, 61 and 100 also declared misbranded under provisions of the law applicable to foods.

DPS Formula 56.—Dartell Professional Service, Los Angeles. Shipped March 26, 1943. Label declared composition to include "Vitamins A, 80,000 USP XI units; Vitamin D, residual amounts as carried with Vitamin A." Product misbranded because falsely represented as effective in nephritis, conjunctivitis, otitis media, kidney stones, eye weakness and some other disorders.—[*D. D. N. J., F. D. C. 1125; June 1945.*]

Floritone.—Manufactured by Vitolectic Food Company, Providence, R. I., and shipped April 12, 1943, by Nature Food Centres, Inc., Providence. Composition: essentially glucose, dextrin and whey powder. Misbranded because label falsely represented that Floritone, taken between meals, would increase weight, and, if taken with meals, would reduce weight, and that when used in large quantities, it would be of benefit in diarrhea and toxemia.—[*D. D. N. J., F. D. C. 1132; June 1945.*]

Genuine O. B. C. Capsules.—William A. Reed Company, Philadelphia. Shipped April 26, May 20 and June 10, 1943. Composition: essentially phenolphthalein, caffeine and clay. Misbranded because of false label representation that the product would effectively reduce weight and because declaration of active ingredients and warnings against use and unsafe dosage or methods or duration of administration were not sufficiently conspicuous.—[*D. D. N. J., F. D. C. 1134 and 1230; June 1945.*]

Hayden's Caramelized Wheat Germ.—Hayden Flour Mills, Inc., Tecumseh, Mich. Shipped May 11, 1943. Misbranded because labeling falsely represented that about 300 pounds of wheat are required to produce one pound of this product; that it would effectively treat constipation, arthritis, retarded growth, gray hair, stomach ulcer, eczema, neuritis, and many other disorders, stimulate the appetite, aid digestion and nerves and produce some other results.—[*D. D. N. J., F. D. C. 1129; June 1945.*] Also misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 5785*.

Hello Minerals.—Gordon Service, Inc., Detroit. Shipped June 7 and July 30, 1943. Composition: seaweed, alfalfa and parsley leaves. Misbranded because (1) name was false and misleading as applied to a mixture of this kind; (2) label claimed that product contained in natural form all minerals known to be essential to nutrition and was especially rich in iron and copper; (3) product was represented to come from the laboratories of an internationally recognized scientist and to supply minerals in amounts sufficient to be of real value, and (4) accompanying literature falsely represented that product, either alone or combined with vitamin B complex, would enrich the blood, soothe the nerves, add energy, repair the body, and produce some other benefits.—[*D. D. N. J., F. D. C. 1131; June 1945.*] Also misbranded under provisions of the law applicable to foods.

Macu Brand Papaya Concentrate.—Macu Fruit Products, Chicago. Shipped April 19, 1943. Composition: papaya pulp and seeds, with sugar. Misbranded because label falsely represented that product, when used as directed, was a rich source of vitamins, a valuable aid to digestion, and helpful in gastritis, diphtheria, ulcers, bowel disorders, dyspepsia, croup, cancer and gastric fermentation.—[*D. D. N. J., F. D. C. 1126; June 1945.*]

Nulfey Tablets.—William A. Reed Company, Philadelphia. Shipped April 26, May 20 and June 10, 1943. Composition: essentially sodium salicylate, sodium biphosphate, methenamine, and plant drugs, including a laxative one. Misbranded because falsely represented in labeling as effective for relief of rheumatism, arthritis, neuritis and sciatica, as well as a diuretic and analgesic offering relief from kidney dysfunction.—[*D. D. N. J., F. D. C. 1134 and 1230; June 1945.*]

Trapper's Preparation for Sinus.—Trapper's Remedies, Inc., Weiser, Ida. Shipped April 15, 1942. Composition: Essentially ground, woody material, not identified. Misbranded because label falsely represented among other things, that preparation would prevent, cure or benefit sinus disease, headache, colds, trench mouth and stomach ulcers, improve circulation and overcome nervousness.—[*D. D. N. J., F. D. C. 1121; June 1945.*]

FILM REVIEWS

Technique of Anaesthesia: A group of eleven 16 mm. sound films depicting various technics used by anesthetists in teaching military personnel of the British armed forces during the war. Available—rental or purchase—through the College Film Center, 84 East Randolph Street, Chicago 1.

These films were made at Westminster Hospital, London, under the supervision of I. W. Magill, director of anesthesia at that institution and senior consultant in anesthesia to the British army. The photographic work was contributed by the Realist Film Unit of London. In several of the films, exceptionally effective use is made of well executed animated drawings. The scenario for each film is well planned to accomplish its purpose. A few unfortunate instances of inattention to detail (e. g. detracting backgrounds and the use of bright metal table tops acting as confusing mirrors) are evident but gratifyingly rare as compared with many medical films. Sound effects are in general well synchronized with action, and the narrator speaks distinctly and slowly as is proper. The British accent will be understood easily by American audiences, but an occasional use of terms uncommon in this country may confuse some listeners. For instance, a "trolley" as the four wheeled conveyance on which patients are transported through the corridors of a hospital may be unfamiliar.

This group of films was produced with the object of aiding in the rapid instruction of medical personnel in time of war. They were designed to deal with technical performance expected of anesthetists under such conditions. No attempt has been made to represent physiologic background or the refinements of technic used in civilian practice. Certain details of procedure and equipment differ from those used in this country, and these may prove somewhat confusing to physicians here. The contribution to safety of constant palpation of the pulse in either the facial or the temporal artery and frequent estimation of the blood pressure by the anesthetist are not emphasized or illustrated as a routine accompaniment of anesthetic procedures. Nevertheless these eleven films are excellently prepared for the purpose for which they were intended. Certain of them may prove very useful in the instruction of American audiences.

I. *Signs and Stages of Anaesthesia* (twenty-three minutes).—As stated in the introductory legend, the classification is based on that of Guedel. Excellent use of animated diagrams makes for clear exposition. It is unfortunate that demarcation of the beginning of plane one and the end of plane four of third stage surgical anesthesia do not correspond exactly with Guedel's description. Illustration of the various planes on clinical cases is masked somewhat by unnecessary covering of the patient's chest and abdomen. These are minor faults, however, and the film will be found very useful in teaching medical students and young anesthetists.

II. *Open Drop Ether* (thirty-one minutes).—An example of excellent photography and, in many cases, of excellent "acting." Probably this film was one of the earliest in the series, for it shows faults which are probably due to the stress of the moment rather than the intention of the anesthetist. The open technic is no longer open when the mask is covered with waterproof material; and, though this method of allowing carbon dioxide to accumulate may be justifiable during induction, it should not be used during maintenance. It is admitted by all that the secret of the method lies in a constant gradual increase of the quantity of ether applied to the mask, and the film shows the very reverse of this. The importance of adding oxygen to the inspired vapor during deep anesthesia is insufficiently stressed. The stages of anesthesia are well illustrated.

III. *Nitrous Oxide-Oxygen-Ether Anaesthesia* (twenty-seven minutes).—The principles and details of the anesthetist's apparatus are shown with the greatest clarity. Excellent animated drawings make for ease of understanding. Since apparatus is designed to accomplish the same purpose the world over, the minor mechanical differences in construction by English and American manufacturers need not confuse an American audience. The use of a basic mixture of 5 parts of nitrous oxide to 1 of oxygen (17.5 per cent) as illustrated in the film might be changed to 4 to 1 in the interest of safety. With certain qualifying comment by the instructor, this film should prove most useful in the teaching of American medical students and others.
